16. Abstract (Limit: 200 words)

Dynamic testing of a cable-to-post attachment for a high-tension cable median barrier design is described in this report. Many variations of a keyway bolt that connected a high-tension cable to an S-shaped steel post were designed and tested. This attachment was found capable of sustaining a target load of approximately 8.00 kips (35.59 kN) when loaded laterally, while releasing the cable vertically at a load close to 1.00 kips (4.45 kN). These loads were selected to develop the full moment capacity of the posts in cable median barriers while ensuring that the cables are not pulled down as the posts deflect.

Six full scale dynamic bogie tests were conducted to test the behavior of the keyway bolt attachments when loaded in a manner similar to an actual crash. These tests showed favorable results and the cable clip developed was recommended for use in the high-tension cable barrier system.

1 INTRODUCTION

1.1 Background

The Midwest Roadside Safety Facility (MwRSF) was contracted to develop a non-proprietary, high-tension, cable median barrier. This barrier was to be developed for use at any location within a median with up to a 4:1 sloped V-ditch. Cable-to-post attachments desired for low-tension cable barriers were disadvantageous because they were designed for impacts from only one direction. It is necessary for cable median barrier attachment hardware to develop the full moment capacity when loaded laterally while releasing vertically at much lower loads to avoid pulling the cable toward the ground with the deformed posts. In addition, the low vertical release load is also necessary to prevent the cable from locking down on the A-pillar of the vehicle of small passenger cars, which could cause the cable to penetrate the occupant compartment. Since cable median barrier crashes may occur from either direction of traffic, the attachment hardware must develop similar strength and release with similar behavior when loaded from either side of the barrier. Therefore, a new connection design was needed to ensure the safety and functionality of the high-tension cable median barrier.

MwRSF designed and tested a keyway bolt connection that was engineered to perform satisfactorily in conjunction with the high-tension cable median barrier. Dynamic tests were performed on cable attachment hardware at various orientations to simulate different stages of the deformed post during a crash [1].

MwRSF previously conducted three full-scale crash tests on the four cable high-tension cable median barrier that utilized a curved keyway bracket cable clip to attach the cables to the posts of the barrier (test nos. 4CMB-1 through 4CMB-3) [2]. The full-scale crash test no. 4CMB-3 consisted of an 1100C vehicle impacting the cable barrier at a speed of approximately 62.0 mph (99.8 km/h) and at an impact angle of 26.7 degrees. This crash test was considered

unacceptable according to the *Manual for Assessing Safety Hardware* (MASH) standards because the cable caused deformations and intrusion into the occupant compartment that could have caused serious injuries. The cause of the failed test was that the cable snagged on the cable-to-post attachments, which caused the cables to be pulled down on the A-pillar of the vehicle.

1.2 Objective

The project had three main objectives: (1) meet/maintain the cable release behavior from the curved keyway bracket design that was previously crash tested by MwRSF, (2) prevent the cable snagging problems that were present in test no. 4CMB-3 as the cables moved up the posts, and (3) simplify and minimize the number of connecting parts in the cable-to-post connection. The attachment needed to satisfy the targeted strength and cable release behavior for lateral and vertical loads. Initially, a minimum lateral pullout load of 6.00 kips (26.69 kN) was required, with a maximum vertical pullout load of 1.00 kips (4.45 kN). However, upon further investigation, it was decided that the lateral load capacity needed to be increased to 8.00 kips (35.59 kN).

Other factors included in the design were affordability and constructability. The newly developed cable attachment needed to be designed without infringing on current cable-to-post connection patents.

1.3 Scope

Because of the unacceptable behavior of the cable bracket attachments used in test no. 4CMB-3, a new cable-to-post attachment needed to be developed that would release the cable vertically to prevent the cable from being pulled down over the A-pillar of the vehicle. A series of component level tests were conducted to evaluate and fine tune the cable-to-post attachment design. The initial design had several variations that were tested and modified in the field tests. The different variations were tested with lateral, vertical, and angled dynamic loads. After the

cable-to-post attachment were determined to exhibit the correct release requirements, a series of dynamic bogie tests were conducted to evaluate the performance of the attachment in the actual cable barrier system.

2 LITERATURE REVIEW

MwRSF investigated high-tension cable barrier connection design patents in previous research [1]. The current patents include: the Cable Safety System (CASS) produced by Trinity Highway Systems, the Gibraltar Cable Barrier System, the U.S. High Tension Cable Barrier System produced by Nucor Marion Steel, Inc., the Safence Barrier developed by Blue Systems AB, and the Wire Rope Safety Fence (WRSF) produced by Brifen USA, Inc. Detailed descriptions of these high-tension cable median barrier attachments can be found in MwRSF report no. TRP-03-200-08, *Design and Evaluation of High-Tension Cable Median Barrier Hardware*.

Component level tests were conducted on the curved keyway brackets that were used in the high-tension cable barrier for test nos. 4CMB-1 through 4CMB-3. The bracket failed at a lateral load of 5.72 kips (25.44 kN). The bracket test with shoulder bolts allowed the cable to release near the target load of 1.00 kips (4.45 kN) [1].

The full scale crash test no. 4CMB-3 consisted of an 1100C vehicle impacting the cable barrier at a speed of approximately 62.0 mph (99.8 km/h) and at an impact angle of 26.7 degrees. This test failed the MASH 3-10 test criteria because the cables were pulled down on the A-pillar of the vehicle which caused deformations and intrusion into the occupant compartment that could have caused serious injuries [2]. In this test, the cables snagged on the shoulder bolts that attached the curved keyway brackets to the posts. Therefore, the cables were not released vertically and locked down on the A-pillar of the vehicle.

3 CABLE ATTACHMENT DESIGN DETAILS

3.1 Introduction

In previous research, MwRSF conducted numerous dynamic bogie tests on cable attachments for the high-tension cable median barrier. Those tests included curved keyway brackets and keyway bolt attachments [1]. The cable attachments were initially required to develop a minimum of 6.00 kips (26.69 kN) of load laterally and a maximum of 1.00 kips (4.45 kN) vertically to fully develop the lateral resistance of the line posts and to prevent the cable from being pulled down by the deformed posts, respectively.

MwRSF conducted component level tests in a load cell jig on a keyway bolt with a button end to improve the design of the cable attachment. The keyway bolt cable-to-post attachment tests were conducted with three main goals: (1) maintain the vertical and horizontal release loads as the curved keyway bracket used in test nos. 4CMB-1 through 4CMB-3, (2) prevent the cable from snagging on the attachment, and (3) simplify the attachment design. After satisfactory test results were obtained, bogie tests with the keyway bolt attachment mounted in the actual high-tension cable barrier system were conducted to verify the dynamic performance of the bolts.

3.2 S3x5.7 Post Jigs

The standard post used in the high-tension cable median barrier was an S3x5.7 (S76x8.5) section. The post was manufactured from ASTM A36 steel and has a cross section in accordance with A6M standards. The post primarily consisted of three major components: two flanges and the connecting web. The flanges were 2.33 in. (59 mm) wide and 0.26 in. (7 mm) thick, while the web was 0.17 in. (4 mm) thick. All testing described herein used S3x5.7 (S76x8.5) posts or sections of S3x5.7 (S76x8.5) posts for mounting the cable attachments.

3.3 Test Configuration

The keyway bolt attachments were tested at different angles to determine the connection strength at different stages of the deformed post. The angle of the test was measured as the angle from the face of the flange of the post to the direction of the force. A 90 degree test was analogous to a lateral load while a 0 degree test was analogous to a vertical load. Any test with an angle between 0 and 90 degrees simulated the loading condition of a partially deformed post. A summary of the tests and conditions are shown in Tables 1 through 3.

Two different keyway designs were used in the tests. The first design, denoted slot and keyway design type 1, consisted of a slot to hold the threaded end of the keyway bolt and a keyway to hold the button end as shown in the top of Figure 1. This design was modified for several tests by grinding off some of the steel around the slot. The "elongated" remark in Tables 1 through 3 indicates that the slot was modified in the field to slightly enlarge the slot. The second design, denoted slot and keyway design type 2, consisted of a hole slightly larger than the diameter of the keyway bolt to hold the threaded end and a keyway to hold the button end as shown in the bottom of Figure 1. Detailed drawings of both keyway designs are shown in Appendix A.

The tests included several variations of nut connections that ranged from using single or double nuts with loose or tight configurations. Tests conducted with the nuts in the "loose" condition were configured with a small gap between the nut(s) and the flange. Tests conducted with the nuts in the "tight" condition were configured with the nut(s) tightened to the flange with a wrench. All other tests were conducted with the nut(s) tightened by hand. The following test configurations were used: 1 single grade 2 nut, 2 grade 2 nuts, 1 grade 5 nut, and 1 grade 8 high-topped nut.

Figure 1. Slot and Keyway Designs (Top=Type 1, Bottom=Type 2)

3.4 Keyway Bolt Attachments

The basic design of the cable-to-post connection tested consisted of a U-shaped bolt with a button on one end and a shoulder and threaded stud on the other end. The threaded end of the keyway bolt was inserted into a slot below the button and fastened to the flange with a nut. The button head was inserted into a keyway that allowed the keyway bolt to straighten and release the cable when subjected to vertical pullout loads. Detailed drawings of the keyway bolt designs are shown in Appendix A. Material specifications for the hardware used in the bogie tests are shown in Appendix B. There were three basic keyway bolt designs that were tested: (1) the C1018 keyway bolt, (2) the modified C1018 keyway bolt, and (3) the A449 keyway bolt.

3.4.1 C1018 Keyway Bolt

For test nos. HTCUB-1 through HTCUB-26, the keyway bolt was made from C1018 galvanized steel. The shaft of the keyway bolt had a diameter of ¼ in. (6 mm). The C1018 keyway bolt is shown in Figure 2. The test matrix for the C1018 keyway bolt is shown in Table 1.

*All tests utilized the type 1 slot and keyway design

3.4.2 Modified C1018 Keyway Bolt

For test nos. HTCUB-27 through HTCUB-30, the keyway bolt was made from C1018 galvanized steel, but the shape of the bolt was modified from the design used in test nos. HTCUB-1 through HTCUB-26. The modified C1018 keyway bolt only contained two bends and had a longer shaft attached to the button end. The modified C1018 keyway bolt is shown in Figure 3. The test matrix for the modified C1018 keyway bolt is shown in Table 2

3.4.3 A449 Keyway Bolt

For test nos. HTCUB-31 through HTCUB-37, the keyway bolt was made from ASTM A449 galvanized steel and had a similar shape as the C1018 keyway bolt design. However, the threads were terminated 3/32 in. (2.38 mm) from the shoulder of the keyway bolt. The A449 keyway bolt is shown in Figure 4. The test matrix for the A449 keyway bolt is shown in Table 3

4 CABLE ATTACHMENT DYNAMIC COMPONENT TESTING

4.1 Purpose

Dynamic performance of the keyway bolts was evaluated with bogie tests before implementation in a full-scale test. These tests were designed to demonstrate the performance of the keyway bolt design when subjected to cable loads at dynamic speeds and to measure the fracture and release loads of the attachment. In addition, the behavior of the keyway bolt connection was observed when loaded at angles that simulated different stages of the deformed post. It should be noted that cable size used in the dynamic bogie tests was ¾"-6x19, and the actual cable size utilized in the high-tension cable barrier system was ¾"-3x7, which is much stiffer in bending.

4.2 Scope

A series of 37 bogie tests were conducted on the keyway bolt connection. These tests consisted of attaching one end of a cable to a bogie and the other end to the keyway bolt which was mounted to the post section and attached to an adjustable plate. The bogie was then set in motion, away from the bracket, placing a dynamic load on the connection until fracture or release of the attachment through the keyway occurred. The target cable speed was 5.0 mph (8.0 km/h) and the cables were loaded at a range of angles between 0 and 90 degrees (0 degrees = parallel to the post flange, 90 degrees = perpendicular to the post flange).

4.3 Test Facility

Physical testing of the keyway bolt attachment was conducted at the MwRSF testing facility which is located at the Lincoln Air Park on the northwest side of the Lincoln Municipal Airport. The facility is approximately 5 miles (8 km) from the University of Nebraska-Lincoln's city campus.

4.4 Equipment and Instrumentation

A variety of equipment and instrumentation was utilized to collect and record data during the dynamic bogie tests including:

- Bogie
- Load Cell
- Accelerometers
- Photography Cameras
- Test Jig

4.4.1 Bogie

A rigid frame bogie was used to pull a cable attached to the keyway bolt attachment as shown in Figure 5. The weight of the bogie was 1,831 lb (831 kg) for test nos. HTCUB-1 through HTCUB-6, 1,827 lb (829 kg) for test nos. HTCUB-7 through HTCUB-10, 1,819 lb (825 kg) for tests nos. HTCUB-11 through HTCUB-20, 1,727 lb (783 kg) for test nos. HTCUB-21 through HTCUB-30, and 1,816 lb (824 kg) for test nos. HTCUB-31 through HTCUB-37.

The bogie guidance track used in test nos. HTCUB-1 through HTCUB-37 consisted of a corrugated steel beam railing to guide the right-side tires of the bogie. A pickup truck was attached to the bogie by a cable and was used to pull the bogie to a target speed of approximately 5.0 mph (8.0 km/h). When the bogie approached the end of the guidance system, the pickup truck braked allowing the bogie to be free rolling when it applied the load to the keyway bolt.

Figure 5. Rigid Frame Bogie on Guidance Track

4.4.2 Accelerometer

An accelerometer system was mounted on the bogie vehicle near its center of gravity to measure the acceleration in the longitudinal, lateral, and vertical directions for test nos. HTCUB-1 through HTCUB-20 and test nos. HTCUB-31 through HTCUB-35. The accelerometer data used only as a backup if the force history could not be determined from the load cell transducer. The accelerometer was not utilized in test nos. HTCUB-21 through HTCUB-30 and HTCUB-36 through HTCUB-37.

The accelerometer, Model EDR-3, was a triaxial piezoresistive accelerometer system developed by Instrumented Sensor Technology (IST) of Okemos, Michigan. The EDR-3 was configured with 256 kB of RAM memory, a range of ±200 g's, a sample rate of 3,200 Hz, and a 1,120 Hz low-pass filter. The "DynaMax 1 (DM-1)" computer software program and a customized Microsoft Excel worksheet were used to analyze and plot the accelerometer data.

4.4.3 Load Cell

A load cell was placed within the testing apparatus to measure the force exerted on the keyway bolt until failure. This load cell was placed in tension between the attachment and the stationary barrier and had a maximum capacity of 50 kips (222 kN).

4.4.4 High-Speed Digital Photography

Two high-speed AOS VITcam digital video cameras with operating speeds of 500 frames/sec were used to record video imagery of the dynamic testing. One camera was placed above the attachment, facing downward, while the other camera was placed at the same height as the attachment, perpendicular to the test jig.

4.4.5 Digital Photography

Two JVC digital video cameras were used to film the dynamic tests. There cameras operated at a speed of 29.97 frames/sec. One camera was placed above the attachment, facing downward, while the other camera was placed at the same height as the attachment, perpendicular to the test jig.

A Nikon D50 digital still camera was also used to record pre- and post-test images of the dynamic tests.

4.4.6 Test Jig

The test jig consisted of a small section of an S3x5.7 (S76x8.5) post that was connected to an adjustable plate and had a slot and keyway cut into the flange. The adjustable plate was connected through a steel tube to a stationary barrier. The steel tube was attached to the mounting plate by a cylindrical joint which allowed a tension load cell to be used to measure the loads. The keyway bolt was attached to the post section with either 1 or 2 nuts. A cable was then looped through the keyway bolt and tied to a bogie that was set in motion, away from the

attachment, at a speed of approximately 5 mph (8 km/h). Drawings of the test setup are shown in Figure 6 and detailed drawings of the test jig are shown in Appendix A.

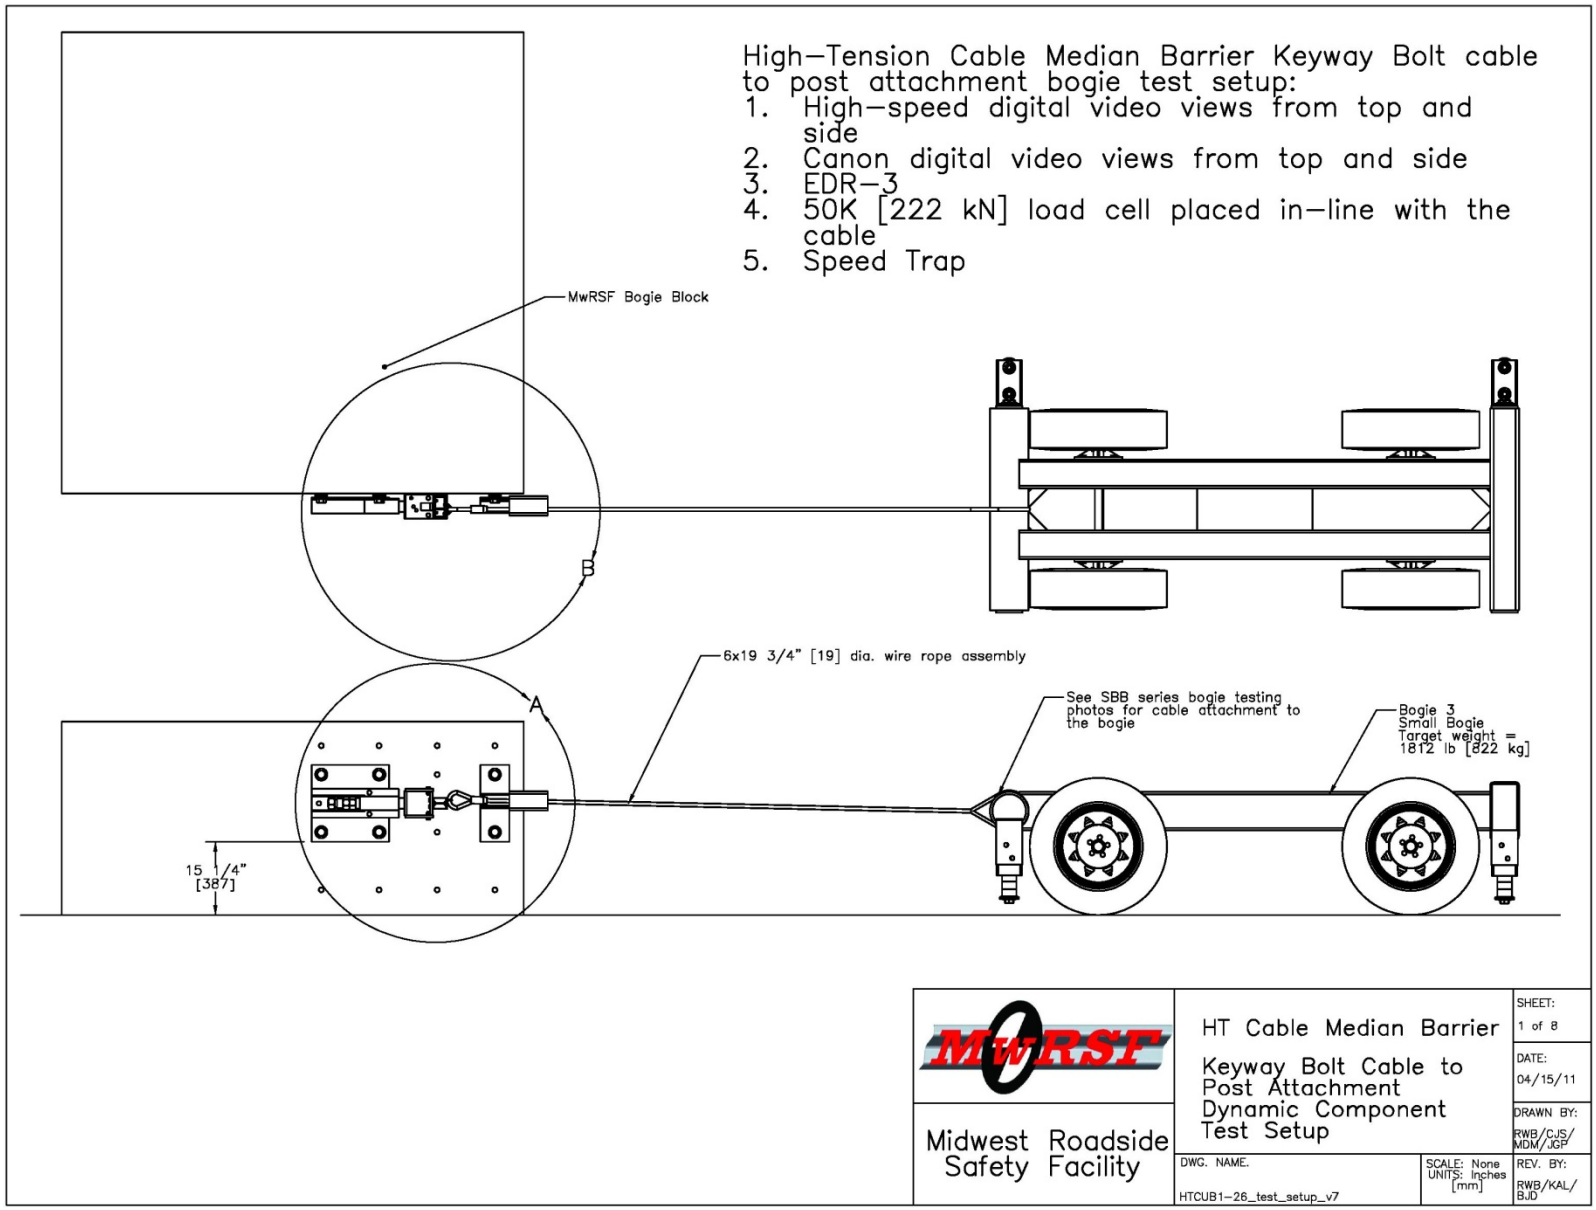

Figure 6. Setup for Test Nos. HTCUB-1 through HTCUB-37

5 COMPONENT DYNAMIC TESTING RESULTS AND DISCUSSION

5.1 Results

A series of 37 dynamic tests were performed on the keyway bolt connection. Vertical, lateral, and inclined loads were applied by varying the angle of the applied load to test its load capacity under different load orientations. The type 1 slot and keyway design was used for the first 26 tests while the type 2 slot and keyway design was used for the last 11. The summary of all test results are shown in Table 4.

Table 4. Dynamic Testing Results Summary

Test	Angle	Nuts	Keyway Bolt	Peak Load	Results
HTCUB-1	90°	Grade 2 - Single - Hand	C1018	5.34 kips (23.75 kN)	Bolt Threads Stripped
HTCUB-2	90°	Grade 2 - Single - Hand	C1018	4.87 kips (21.66 kN)	Bolt Threads Stripped
HTCUB-3	90°	Grade 2 - Double - Hand	C1018	6.71 kips (29.85 kN)	Bolt Fracture Through Threads
HTCUB-4	90°	Grade 2 - Double - Hand	C1018	5.74 kips (25.53 kN)	Bolt Fracture Through Threads
HTCUB-5	0°	Grade 2 - Double - Hand	C1018	2.25 kips (10.01 kN)	Released - Button Through Keyway
HTCUB-6	0°	Grade 2 - Double - Hand	C1018	1.71 kips (7.61 kN)	Released - Button Through Keyway
HTCUB-7	0°	Grade 2 - Double - Loose	C1018	N/A	Released - Button Through Keyway
HTCUB-8	0°	Grade 2 - Double - Loose	C1018	1.04 kips (4.63 kN)	Released - Button Through Keyway
HTCUB-9	0°	Grade 2 - Double - Loose	C1018	1.02 kips (4.54 kN)	Released - Button Through Keyway
HTCUB-10	0°	Grade 2 - Double - Loose	C1018	0.49 kips (2.18 kN)	Released - Button Through Keyway

HTCUB-35	0°	Grade 8 - Single - Tight	A449	1.41 kips (6.27 kN)	Released - Button Through Keyway
HTCUB-36	0°	Grade 8 - Single - Tight	A449	1.27 kips (5.65 kN)	Released - Button Through Keyway
HTCUB-37	0°	Grade 8 - Single - Tight	A449	0.92 kips (4.09 kN)	Released - Button Through Keyway

5.1.1 Test No. HTCUB-1

For test no. HTCUB-1, the cable applied a load to the keyway bolt at an angle of 90 degrees from the face of the flange. The keyway bolt was attached with one grade 2 nut positioned at the center of the slot. Force data was measured with the load cell transducer and the data was processed with the Channel Frequency Class (CFC) 60 filter in accordance with the Society of Automotive Engineers (SAE) J211. The start of the test was determined as the first data point opposite in sign from the polarity of the main acceleration signal. The cable released at a load of 5.34 kips (23.75 kN). The nut stripped off the threads and the keyway bolt straightened out. The force versus time plot is shown in Figure 7. Pre- and post-test photographs are shown in Figure 8. Sequential photographs are shown in Figure 9.

5.1.2 Test No. HTCUB-2

For test no. HTCUB-2, the cable applied a load the keyway bolt at an angle of 90 degrees from the face of the flange. The keyway bolt was attached with one grade 2 nut positioned at the center of the slot. The cable released at a load of 4.87 kips (21.66 kN). The nut stripped off the threads and the keyway bolt straightened out. The force versus time plot is shown in Figure 10. Pre- and post-test photographs are shown in Figure 11. Sequential photographs are shown in Figure 12.

5.1.3 Test No. HTCUB-3

For test no. HTCUB-3, the cable applied a load to the keyway bolt at an angle of 90 degrees from the face of the flange. The keyway bolt was attached with two grade 2 nuts positioned at the center of the slot. The cable released at a load of 6.71 kips (29.85 kN). The keyway bolt fractured through the threads and straightened out. The force versus time plot is shown in Figure 13. Pre- and post-test photographs are shown in Figure 14. Sequential photographs are shown in Figure 15.

5.1.4 Test No. HTCUB-4

For test no. HTCUB-4, the cable applied a load to the keyway bolt at an angle of 90 degrees from the face of the flange. The keyway bolt was attached with two grade 2 nuts positioned at the center of the slot. The cable released at a load of 5.74 kips (25.53 kN). The keyway bolt fractured through the threads and straightened out. The force versus time plot is shown in Figure 16. Pre- and post-test photographs are shown in Figure 17. Sequential photographs are shown in Figure 18.

Time = 170 ms Time = 172 ms

Figure 18. Sequential Photographs, Test No. HTCUB-4

5.1.5 Test No. HTCUB-5

For test no. HTCUB-5, the cable applied a load to the keyway bolt at an angle of 0 degrees, parallel to the face of the flange. The keyway bolt was attached with two grade 2 nuts positioned at the bottom of the slot and the button head of the bolt was at the lowest position in the keyway. The cable released at a load of 2.25 kips (10.01 kN). The button slipped out of the keyway while the threaded end remained attached to the flange and the keyway bolt straightened out. The force versus time plot is shown in Figure 19. Pre- and post-test photographs are shown in Figure 20. Sequential photographs are shown in Figure 21.

5.1.6 Test No. HTCUB-6

For test no. HTCUB-6, the cable applied a load to the keyway bolt at an angle of 0 degrees, parallel to the face of the flange. The keyway bolt was attached with two grade 2 nuts positioned at the upper-center of the slot. The cable released at a load of 1.71 kips (7.61 kN). The button slipped out of the keyway while the threaded end remained attached to the flange and the keyway bolt straightened out. The force versus time plot is shown in Figure 22. Pre- and post-test photographs are shown in Figure 23. Sequential photographs are shown in Figure 24.

5.1.7 Test No. HTCUB-7

For test no. HTCUB-7, the cable applied a load to the keyway bolt at an angle of 0 degrees, parallel to the face of the flange. The keyway bolt was attached with a small gap between the two grade 2 nuts and the flange. The threaded end was positioned at the lower-center of the slot. Due to technical difficulties, the load cell did not collect load data. The button slipped out of the keyway while the threaded end remained attached to the flange and the keyway bolt straightened out. Pre- and post-test photographs are shown in Figure 25. Sequential photographs are shown in Figure 26.

Time = 130 ms Time = 134 ms

Figure 26. Sequential Photographs, Test No. HTCUB-7

5.1.8 Test No. HTCUB-8

For test no. HTCUB-8, the cable applied a load to the keyway bolt at an angle of 0 degrees, parallel to the face of the flange. The keyway bolt was attached with a small gap between the two grade 2 nuts and the flange. The threaded end was positioned at the lower-center of the slot. The cable released at a load of 1.04 kips (4.63 kN). The button slipped out of the keyway while the threaded end remained attached to the flange and the keyway bolt straightened out. The force versus time plot is shown in Figure 27. Pre- and post-test photographs are shown in Figure 28. Sequential photographs are shown in Figure 29.

5.1.9 Test No. HTCUB-9

For test no. HTCUB-9, the cable applied a load to the keyway bolt at an angle of 0 degrees, parallel the face of the flange. The keyway bolt was attached with a small gap between the two grade 2 nuts and the flange. The threaded end was positioned at the lower-center of the slot. The cable released at a load of 1.02 kips (4.54 kN). The button slipped out of the keyway while the threaded end remained attached to the flange and the keyway bolt straightened out. The force versus time plot is shown in Figure 30. Pre- and post-test photographs are shown in Figure 31. Sequential photographs are shown in Figure 32.

Figure 32. Sequential Photographs, Test No. HTCUB-9

5.1.10 Test No. HTCUB-10

For test no. HTCUB-10, the cable applied a load to the keyway bolt at an angle of 0 degrees, parallel to the face of the flange. The keyway bolt was attached with a small gap between the two grade 2 nuts and the flange. The threaded end was positioned at the bottom of the lower slot in the post, which was slightly elongated towards the keyway. The elongation of the slot was done to allow for the button to release more easily. The cable released at a load of 0.49 kips (2.18 kN). The button slipped out of the keyway while the threaded end remained attached to the flange and the keyway bolt straightened out. The force versus time plot is shown in Figure 33. Pre- and post-test photographs are shown in Figure 34. Sequential photographs are shown in Figure 35.

5.1.11 Test No. HTCUB-11

For test no. HTCUB-11, the cable applied a load to the keyway bolt at an angle of 0 degrees, parallel to the face of the flange. The keyway bolt was attached with two grade 2 nuts positioned at the center of the lower slot. The shoulder of the keyway bolt was ground off. The cable released at a load of 2.12 kips (9.43 kN). The button slipped out of the keyway while the threaded end remained attached to the flange and the keyway bolt straightened out. The force versus time plot is shown in Figure 36. Pre- and post-test photographs are shown in Figure 37. Sequential photographs are shown in Figure 38.

5.1.12 Test No. HTCUB-12

For test no. HTCUB-12, the cable applied a load to the keyway bolt at an angle of 0 degrees, parallel to the face of the flange. The keyway bolt was attached with two grade 2 nuts tightened with a wrench that were positioned at the top of the elongated, lower slot. The slot that held the threaded end of the keyway bolt was slightly elongated. The cable released at a load of 0.56 kips (2.49 kN), but the cable snagged on the button and released at a load of 0.58 kips (2.58 kN). The button slipped out of the keyway while the threaded end remained attached to the flange and the keyway bolt straightened out. The force versus time plot is shown in Figure 39. Pre- and post-test photographs are shown in Figure 40. Sequential photographs are shown in Figure 41.

5.1.15 Test No. HTCUB-15

For test no. HTCUB-15, the cable applied a load to the keyway bolt at an angle of 0 degrees, parallel to the face of the flange. The keyway bolt was attached with two grade 2 nuts tightened with a wrench that were positioned at the bottom of the slot. The slot that held the threaded end of the keyway bolt was slightly elongated and the size of the button was slightly reduced. The cable released at a load of 0.88 kips (3.91 kN), but the cable snagged on the button an released at a load of of 1.00 kips (4.45 kN). The button slipped out of the keyway while the threaded end remained attached to the flange and the keyway bolt straightened out. The force versus time plot is shown in Figure 48. Pre- and post-test photographs are shown in Figure 49. Sequential photographs are shown in Figure 50.

For test no. HTCUB-24, the cable applied a load to the keyway bolt at an angle of 45 degrees from the face of the flange. The keyway bolt was attached with two grade 2 nuts tightened with a wrench that were positioned at the top of the slot. The slot that held the threaded end of the keyway bolt was slightly elongated. The cable released at a load of 0.74 kips (3.29 kN), but the cable snagged on the button and released at a load of 1.61 kips (7.16 kN). The button slipped out of the keyway while the threaded end remained attached to the flange and the keyway bolt straightened out. The force versus time plot is shown in Figure 75. Pre- and post-test photographs are shown in Figure 76. Sequential photographs are shown in Figure 77.

5.2 Discussion

The 37 dynamic tests were used to evaluate the cable clip hardware and develop a design that could be utilized in the high-tension cable median barrier. The design objectives required the cable clip to maintain a minimum perpendicular tensile load of 8.00 kips (35.59 kN) while releasing vertically at a maximum pullout load of 1.00 kips (4.45 kN). Several different configurations were tested with different sizes and strengths of nuts, keyway bolts, and slot and keyway designs.

The type 1 slot and keyway was designed for development only and was used to fine tune the bolt attachment. The testing of the type 1 slot and keyway design led to the type 2 design in terms of the depth and position of the keyway relative to the lower hole. The type 2 slot and keyway design showed more consistent behavior and an improvement over the type 1 design. Placement of the top arm of the bolt lower in the keyway led to the upper arm having higher release loads. This led to excessive loads in tests which utilized the type 1 design and the keyway bolt placed near the bottom of the slot. These failed tests included HTCUB-5, HTCUB-6, HTCUB-11, HTCUB-14, and HTCUB-16 because the observed loads were higher than the maximum acceptable vertical pullout load for the C1018 keyway bolt.

Following test nos. HTCUB-1 through HTCUB-30, it was believed that the C1018 keyway bolt with either a single grade 5 nut or double grade 2 nuts installed on the type 2 slot and keyway design would yield the desired behavior. However, after observing the first two cable barrier dynamic bogie tests described in Chapter 7 (HTCC-1 and HTCC-2), the design requirements were considered inadequate because the clips prematurely released the cables due to fracture of the bolt and did not develop the desired deformation of the S3x5.7 (S76x8.5) post. An A449 keyway bolt with a single grade 8 high-topped nut was proposed and tested in order to

increase the strength of the cable clip connection. The selection of the thicker grade 8 nut was to prevent the threads from stripping off of the bolts, as was observed in test nos. HTCUB-1 and HTCUB-2. Both of the 90 degree tests that utilized the A449 keyway bolt and the grade 8 high-topped nut provided a resistance greater than 8.00 kips (35.59 kN) while releasing the cable at an average load of 1.18 kips (5.25 kN) for the 0 degree tests. The increase in vertical pullout loads, although undesirable, was accepted in exchange for greater tensile capacity. This design showed favorable results and was recommended for implementation in the high-tension cable barrier design after verifying its performance when installed on the S3x5.7 (S76x8.5) posts with dynamic bogie testing.

6 CABLE BARRIER DYNAMIC BOGIE TESTING

6.1 Purpose

Six dynamic bogie tests were performed to evaluate the high-tension cable barrier attachments when installed on a series of S3x5.7 (S76x8.5) posts with a high-tension cable and subjected to loads in a similar manner as a full-scale crash. It was desired that the keyway bolts develop the full strength of the post when the posts were in the vertical position, while allowing the cable to release from the posts as the posts deformed and rotated toward the ground. The clips were designed to develop the full moment capacity of the steel posts with specified yield strengths up to 50 ksi (345 MPa). The test was considered successful if the clips developed enough load to deform the post, but released the cable at a similar post rotation to the curved keyway bracket attachment used in full-scale crash test nos. 4CMB-1 through 4CMB-3.

6.2 Scope

The basic test setup consisted of four S3x5.7 (S76x8.5) posts at 16 ft (1.88 m) spacing with a tensioned cable mounted along all four posts, as shown in Figure 116. A bogie was directed toward the cable barrier and at the midpoint between post nos. 4 and 5. The target conditions were 17.0 mph (27.4 km/h) at an angle of 90 degrees to the cable. The cable was set at a height of 34-1/2 in. (876 mm) above the ground surface. A summary of all the cable barrier dynamic bogie tests is shown in Table 5. All of the posts were placed in a compacted coarse, crushed limestone material meeting Grading B of AASHTO M 147-65 as found in MASH.

For test no. HTCC-1, two different types of attachments were used. The two posts adjacent to the impact location utilized C1018 galvanized steel keyway bolts with the type 2 slot and keyway and one grade 5 nut. The test setup drawings used for test no. HTCC-1 are shown in Figures 116 through 119. Post no. 4 was oriented so that the cable was on the non-impact side of the post and post no. 5 was oriented so that the cable was on the impact side of the post. This

allowed for evaluating the performance of the attachment when the cable was pulled away and pushed into the post. Post nos. 3 and 6 utilized a curved keyway bracket with shoulder bolts on the non-impact side of the posts. MwRSF previously performed static and dynamic testing on this clip design [1]. Material specifications for all hardware used in the bogie tests are shown in Appendix B.

Test no. HTCC-2 was set up with a similar configuration as test no. HTCC-1. The test setup for test no. HTCC-2 is shown in Appendix A. Both post nos. 4 and 5 had the cable connected to the non-impact side of the post with C1018 galvanized steel keyway bolts. Post no. 4 had one grade 5 nut attached to the keyway bolt while post no. 5 had two grade 2 nuts attached to the keyway bolt. Post nos. 3 and 6 utilized curved keyway brackets with shoulder bolts installed on the non-impact side of the posts.

Test nos. HTCC-3 and HTCC-4 were set up with a similar configuration as test no. HTCC-1. The test setup used in test nos. HTCC-3 and HTCC-4 is shown in Appendix A. Test no. HTCC-3 utilized C1018 galvanized steel keyway bolts with grade 8 high-topped nuts on post nos. 4 and 5. Test no. HTCC-4 utilized A449 galvanized steel keyway bolts with grade 8 high-topped nuts on post nos. 4 and 5. For both test nos. HTCC-3 and HTCC-4, post nos. 3 and 6 utilized curved keyway brackets with shoulder bolts installed on the non-impact side of the posts. Test no. HTCC-5 was a repeat test of test no. HTCC-4. The keyway bolts used in test nos. HTCC-3, HTCC-4, and HTCC-5 had the threads terminated 3/32 in. (2.38 mm) from the shoulder of the keyway bolt.

Test no. HTCC-6 was set up with a similar configuration to the previous tests except that the curved keyway brackets with shoulder bolts were utilized at every post connection. The test setup drawings for test no. HTCC-6 are shown in Appendix A. Post nos. 3, 4, and 6 had the

curved keyway brackets installed on the non-impact side of the post while post no. 5 had the curved keyway bracket installed in the impact side of the post.

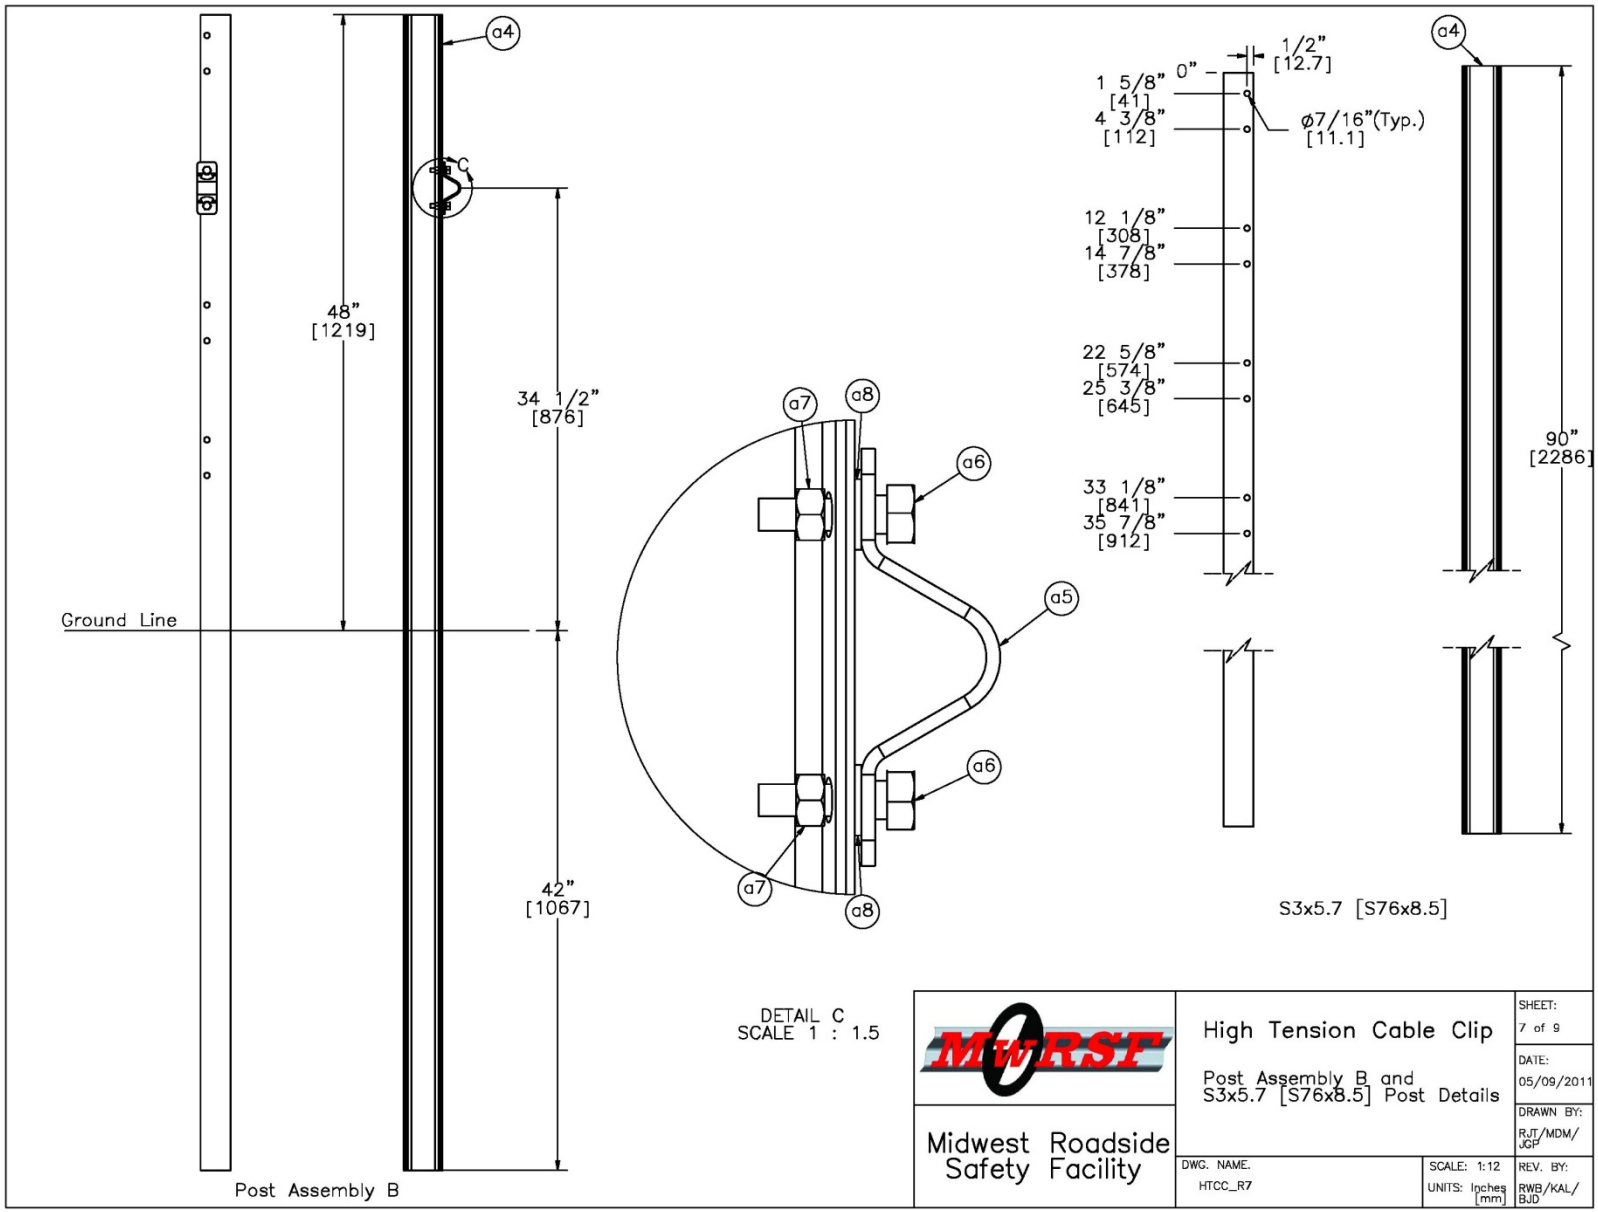

Figure 119. Post Assembly B, Test No. HTCC-1

6.3 Test Facility

Physical testing of the high-tension cable barrier was conducted at the MwRSF testing facility which is located at the Lincoln Air Park on the northwest side of the Lincoln Municipal Airport. The facility is approximately 5 miles (8 km) from the University of Nebraska-Lincoln's city campus.

Table 5. Summary of Bogie Crash Test Setups

Test No.	Post No. 3	Post No. 4	Post No. 5	Post No. 6	Bogie Speed	Cable Tension
HTCC-1	Curved Keyway Bracket on Non-Impact Side	C1018 Keyway Bolt with Grade 5 Nut on Non-Impact Side	C1018 Keyway Bolt with Grade 5 Nut on Impact Side	Curved Keyway Bracket on Non-Impact Side	19.6 mph (31.5 km/h)	4.12 kips (18.33 kN)
HTCC-2	Curved Keyway Bracket on Non-Impact Side	C1018 Keyway Bolt with Grade 5 Nut on Non-Impact Side	C1018 Keyway Bolt with Two Grade 2 Nuts on Non-Impact Side	Curved Keyway Bracket on Non-Impact Side	18.5 mph (29.8 km/h)	3.98 kips (17.70 kN)
HTCC-3	Curved Keyway Bracket on Non-Impact Side	C1018 Keyway Bolt with Grade 8 High-Topped Nut on Non-Impact Side	C1018 Keyway Bolt with Grade 8 High-Topped Nut on Impact Side	Curved Keyway Bracket on Non-Impact Side	20.1 mph (32.3 km/h)	4.14 kips (18.42 kN)
HTCC-4	Curved Keyway Bracket on Non-Impact Side	A449 Keyway Bolt with Grade 8 High-Topped Nut on Non-Impact Side	A449 Keyway Bolt with Grade 8 High-Topped Nut on Impact Side	Curved Keyway Bracket on Non-Impact Side	21.4 mph (34.4 km/h)	4.10 kips (18.24 kN)

6.4 Equipment and Instrumentation

A variety of equipment and instrumentation was utilized to collect and record data during the dynamic bogie tests that included:

- Bogie
- Accelerometers
- Pressure Tape Switches
- Photography Cameras

6.4.1 Bogie

A rigid frame bogie with a variable height, detachable head was used to impact the cable barrier. The bogie impact head was attached to the front of the bogie, with the horizontal tube oriented above the cable. A photograph of the bogie with the head in position relative to the height of the cable is shown in Figure 120.

The tests were conducted using a steel corrugated beam guardrail to guide the left-side tires of the bogie vehicle. A pickup truck was used to accelerate the bogie vehicle to the required impact velocity. After reaching the target velocity, the push vehicle braked allowing the bogie to be free rolling as it came off the track.

6.4.2 Accelerometers

An accelerometer system was mounted on the bogie vehicle near its center of gravity to measure the acceleration in the longitudinal, lateral, and vertical directions. The accelerometer, Model EDR-3, was a triaxial piezoresistive accelerometer system developed by Instrumented Sensor Technology (IST) of Okemos, Michigan. The EDR-3 was configured with 256 kB of RAM memory, a range of ±200 g's, a sample rate of 3,200 Hz, and a 1,120 Hz low-pass filter. The "DynaMax 1 (DM-1)" computer software program and a customized Microsoft Excel worksheet were used to analyze and plot the accelerometer data.

Figure 120. Rigid Frame Bogie with Head Attachment and Cable Height

An additional accelerometer system was used to measure the acceleration in the longitudinal and lateral directions at a sample rate of 10,000 Hz. The environmental shock and vibration sensor/recorder system, a two-Arm piezoresistive accelerometer, was developed by Endevco of San Juan Capistrano, California. Two accelerometers were used to measure the longitudinal and lateral accelerations independently. Data was collected using a Sensor Input Module (SIM), Model TDAS3-SIM-16M, which was developed by Diversified Technical Systems, Inc (DTS) of Seal Beach, California. The SIM was configured with 16 MB SRAM memory and 8 sensor input channels with 250 kB SRAM/channel. The SIM was mounted on a TDAS3-R4 module rack. The module rack is configured with isolated

power/event/communications, 10BaseT Ethernet and RS232 communication, and an internal back-up battery. Both the SIM and module rack were crashworthy. The "DTS TDAS Control" and "DADiSP" computer software programs and a customized Microsoft Excel worksheet were used to analyze and plot the accelerometer data.

6.4.3 Pressure Tape Switches

Three pressure tape switches, spaced at approximately 18-in. (457-mm) intervals and placed near the end of the bogie track, were used to determine the speed of the bogie before the impact. As the right-front tire of the bogie passed over each tape switch, a strobe light was fired sending an electronic timing signal to the data acquisition system. The system recorded the signals and the time each occurred. The speed was then calculated using the spacing between the sensors and the time between the signals. Strobe lights and high-speed video analysis are used only as a backup in the event that vehicle speeds cannot be determined from the electronic data.

6.4.4 Photography Cameras

High-speed AOS VITcam digital video cameras and JVC digital video cameras were used to document each test. All high-speed AOS VITcam digital video cameras had a frame rate of 500 frames per second and all JVC digital video cameras had a frame rate of 29.97 frames per second. A Nikon D50 digital still camera was also used to document pre- and post-test conditions for all tests.

For test nos. HTCC-1 and HTCC-2, two AOS VITcam high-speed digital video cameras were positioned along the cable barrier, with one located downstream of the impact location and the other located upstream of the impact location. Two JVC digital video cameras were also positioned along the cable barrier, with one located downstream of the impact location and the other located upstream of the impact location. Test no. HTCC-2 utilized an additional AOS

VITcam high-speed digital video camera positioned offset of the cable barrier on the non-impact side.

For test nos. HTCC-3, HTCC-4, HTCC-5, and HTCC-6, three AOS VITcam high speed digital video cameras were used with one positioned downstream and offset to the impact side of the impact location, one positioned upstream and offset to the non-impact side of the impact location, and one positioned along the cable barrier on the upstream end. Three JVC digital video cameras were also used and were positioned in the same locations as the AOS VITcam high speed digital cameras.

7 CABLE BARRIER TESTING RESULTS AND DISCUSSION

7.1 Results

Six dynamic bogie tests were performed to evaluate the dynamic performance of the keyway bolt attachment in the vicinity of impact. The tested keyway bolts with the type 2 slot and keyway design and/or the curved keyway bracket with shoulder bolts were installed on posts on both sides of impact. A summary of the test results is shown in Table 6. For each test, a measurement of the maximum strong axis post bend angle was taken from either post no. 4 or 5. The reported bend angle was taken from the post that experienced the least rotation of the two.

7.1.1 Test No. HTCC-1

For test no. HTCC-1, a tensile pre-load of 4.12 kips (18.33 kN) was applied to the cable. The 4,913 lb (2,228 kg) bogie impacted the cable barrier at a speed of 19.6 mph (31.5 km/h) at the midspan between post nos. 4 and 5 at an angle of 90 degrees from the cable. The C1018 keyway bolt that was installed on post no. 4 fractured in tension through the threads at the base of the shoulder while the keyway bolt that was installed on post no. 5 released the cable when the button slipped out of the keyway. All of the posts yielded near the ground line and experienced some slight twisting deformation. Pre- and post-test photographs of the bogie and system are shown in Figure 121. Pre- and post-test photographs of the attachments are shown in Figures 122 and 123, and sequential photographs are shown in Figure 124. There was significant scraping damage to the keyway on post no. 5, as shown in Figure 123. The cable also scraped the edge of the flange from the keyway location to the top of the post. There was no significant damage to the keyway on post no. 4. The maximum angle of rotation of the posts was 18 degrees, as shown in Figure 125.

Table 6. Summary of Bogie Crash Tests

7.1.2 Test No. HTCC-2

For test no. HTCC-2, a tensile pre-load of 3.98 kips (17.70 kN) was applied to the cable. The 4,926 lb (2,234 kg) bogie impacted the cable barrier at a speed of 18.5 mph (29.8 km/h) at the midspan between post nos. 4 and 5 at an angle of 90 degrees from the cable. Both of the C1018 keyway bolts on post nos. 4 and 5 fractured in tension through the threads at the base of the shoulder. All of the posts yielded near the ground line and experienced some slight twisting deformation. There were slight contact marks around the edges of the slots and keyways that were caused by the impact with the keyway bolt. The angle of post rotation was not able to be determined for this test because there was not a camera aligned along the line of the posts. However, the post behavior was very similar to the post deformation observed in test no. HTCC-1. Pre- and post-test photographs of the bogie and system are shown in Figure 126. Pre- and post-test photographs of the attachments are shown in Figures 127 and 128. Sequential photographs are shown in Figure 129.

7.1.3 Test No. HTCC-3

For test no. HTCC-3, a tensile pre-load of 4.14 kips (18.42 kN) was applied to the cable. The 4,937 lb (2,239 kg) bogie impacted the cable barrier at a speed of 20.1 mph (32.3 km/h) at the midspan between post nos. 4 and 5 at an angle of 90 degrees from the cable. The C1018 keyway bolt that was installed on post no. 4 fractured in tension through the threads while the keyway bolt that was installed on post no. 5 released the cable when the button slipped out of the keyway. All of the posts yielded near the ground line and experienced some slight twisting deformation. Post no. 4 had slight contact marks from the impact with the keyway bolt and post no. 5 had scrape marks from the impact with the cable. The maximum angle of rotation of the posts was 23 degrees, as shown in Figure 130. Pre- and post-test photographs of the bogie and system are shown in Figure 131. Pre- and post-test photographs of the attachments are shown in Figures 132 and 133. Sequential photographs are shown in Figure 134.

7.1.4 Test No. HTCC-4

For test no. HTCC-4, a tensile pre-load of 4.10 kips (18.24 kN) was applied to the cable. The 4,937 lb (2,239 kg) bogie impacted the cable at a speed of 21.4 mph (34.4 km/h) at the midspan between post nos. 4 and 5 at an angle of 90 degrees from the cable. The A449 keyway bolt that was installed on post no. 4 fractured in tension through the threads while the A449 keyway bolt that was installed on post no. 5 released the cable when the button slipped out of the keyway. All of the posts yielded near the ground line and experienced some twisting deformation. However, post no. 5 experienced a larger angle of bending that post no. 4. Post no. 4 had slight contact marks from the impact with the keyway bolt and post no. 5 had scrape marks from the impact with the cable. The maximum angle of rotation of the posts was 34 degrees, as shown in Figure 135. Pre- and post-test photographs of the bogie and system are shown in Figure 136. Pre- and post-test photographs of the attachments are shown in Figures 137 and 138. Sequential photographs are shown in Figure 139.

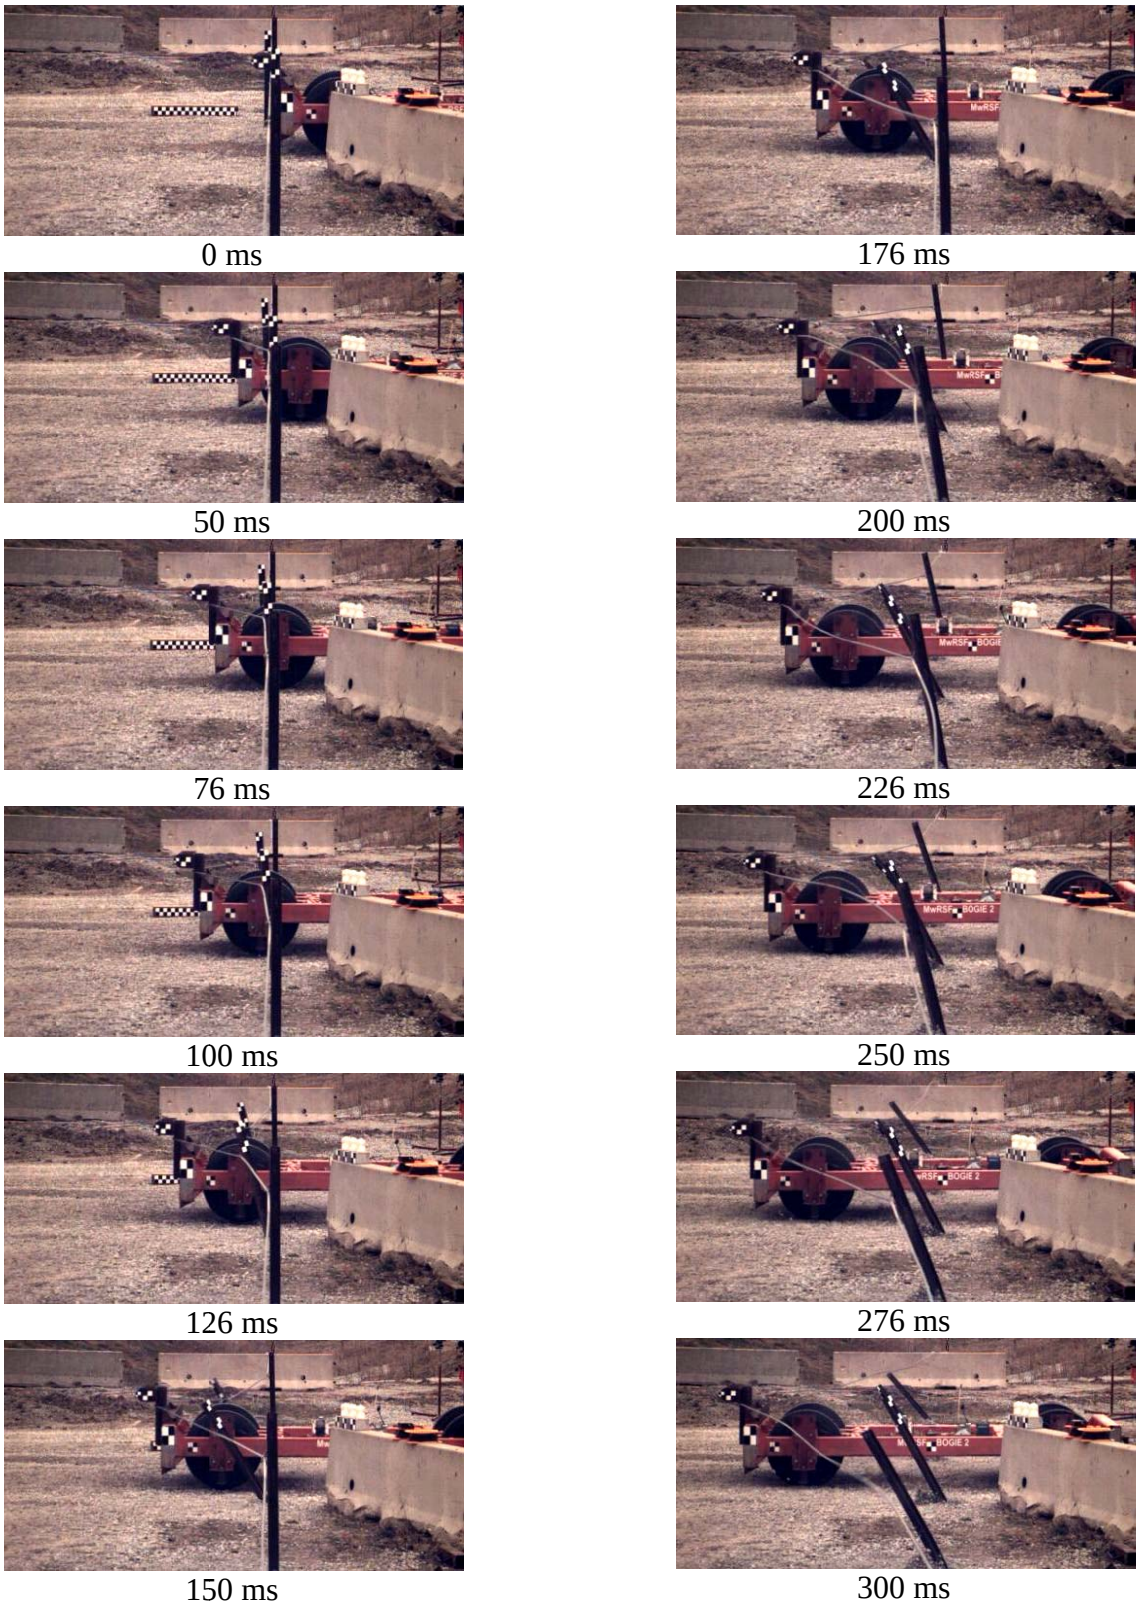

Figure 139. Sequential Photographs, Test No. HTCC-4

7.1.5 Test No. HTCC-5

Test no. HTCC-5 was set up the same as test no. HTCC-4 and experienced similar results. A tensile pre-load of 4.10 kips (18.24 kN) was applied to the cable. The 4,937 lb (2,239 kg) bogie impacted the cable at a speed of 20.8 mph (33.5 km/h) at the midspan between post nos. 4 and 5 at an angle of 90 degrees from the cable. The keyway bolt that was installed on post no. 4 fractured in tension through the threads while the keyway bolt that was installed on post no. 5 released the cable when the button slipped out of the keyway. All of the posts yielded near the ground line and experienced some twisting deformation. Post no. 4 had slight contact marks from the impact with the keyway bolt and post no. 5 had scrape marks from the impact with the cable. A post-test photograph of the bogie and system is shown in Figure 140. Post-test photographs of the attachments are shown in Figures 141 and 142. Sequential photographs are shown in Figure 143. The maximum angle of rotation of the posts was 24 degrees, as shown in Figure 144.

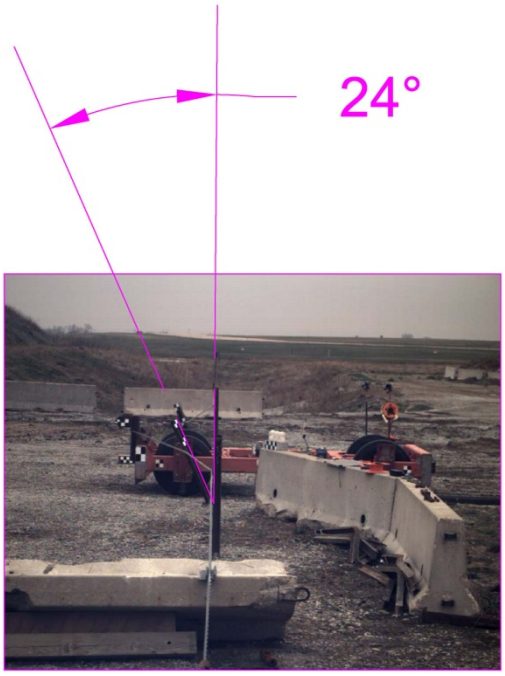

Figure 144. Post Deflection Angle, Test No. HTCC-5

7.1.6 Test No. HTCC-6

For test no. HTCC-6, a tensile pre-load of 4.10 kips (18.24 kN) was applied to the cable. The 4,937 lb (2,239 kg) bogie impacted the cable at a speed of 19.8 mph (31.9 km/h) at the midspan between post nos. 4 and 5 at an angle of 90 degrees from the cable. The clip on post no. 4 straightened out and released the cable as the shoulder bolt slipped through the keyway on the cable clip. The clip on post no. 5 also straightened out and released the clip from the shoulder bolts, but the cable snagged on the top shoulder bolt which fractured in shear and released the cable. All of the posts yielded near the ground line and experienced some twisting deformation. There were scrape marks on post no. 5 from the impact with the cable and the top shoulder bolt was fractured off. The maximum angle of rotation of the posts was 33 degrees, as shown in Figure 145. Pre- and post-test photographs of the system are shown in Figure 146. Pre- and post-test photographs of the attachments are shown in Figures 147 and 148. Sequential photographs are shown in Figure 149. There was little damage around the connection area on post no. 4.

7.2 Discussion

Six dynamic bogie tests were conducted to evaluate the performance and behavior of the high-tension cable barrier with the clips developed. The tests were conducted with both C1018 and A449 keyway bolts and the curved keyway bracket design used in the full-scale crash test nos. 4CMB-1 through 4CMB-3. Results from these tests were analyzed to ensure that the keyway bolt cable attachments could safely release the cables while still developing similar levels of post deformation and post energy absorption as the original curved keyway bracket.

Test no. HTCC-6 utilized the curved keyway bracket at every post connection. This test was used as a baseline comparison for the keyway bolt attachments. It should be noted that a cable snag on the shoulder bolt installed on the impact side of the post was observed in this test. This behavior is not desired as it could lead to unacceptable behavior of the system if the cables slip over the hood of a vehicle. This behavior was documented in a previous test report [2].

The results from test nos. HTCC-1 and HTCC-2 showed consistent release of the cable, but the cable released from the posts too quickly and insufficient post deformation and rotation was achieved. Test nos. HTCC-3, HTCC-4, and HTCC-5 utilized higher strength keyway bolts and/or nuts to increase the connection strength. In addition, the threads on the keyway bolt were moved away from the shoulder to remove a stress concentration in that area. The maximum post rotation achieved in test no. HTCC-3 was 23 degrees, which was less than the desired post rotation of 33 degrees that was achieved with the curved keyway bracket design utilized is test no. HTCC-6. This lower rotation angle was caused by the premature fracturing of the C1018 keyway bolt on post no. 4. The maximum post rotation angles achieved in test nos. HTCC-4 and HTCC-5 were 34 and 24 degrees respectively. The use of higher strength hardware enabled the keyway bolts to remain attached to the cable longer and the full strength of the posts were developed. This allowed for the posts located near the impact location to absorb more energy.

The behavior of these tests proved to be satisfactory as the clips released the cables without dragging the posts to the ground or uprooting them, causing excessive twisting. Therefore, the A449 keyway bolt with the grade 8 high-topped nut configuration was considered to behave similar to the curved keyway bracket utilized in test no. HTCC-6 because similar maximum post rotation angles were achieved.

Based on the results from the dynamic cable barrier bogie tests, the A449 keyway bolt with the grade 8 high-topped nut used in conjunction with the type 2 slot and keyway design was recommend for use in a full-scale crash test. Three criteria were used to support this design: (1) the keyway bolt attachment exhibited similar post deflection as the curved keyway bracket used in test no. HTCC-6 and test nos. 4CMB-1 through 4CMB-3, (2) there was no evidence that the keyway bolt would cause significant snagging of the cable that would restrict the cable from releasing, and (3) the keyway bolt attachment design was a simpler, less expensive design as compared to the curved keyway bracket attachment.

8 SUMMARY AND CONLUSIONS

Cable-to-post attachment components for the high-tension cable median barrier were selected through a process of dynamic component tests and dynamic bogie tests of a section of the cable barrier system. These tests were designed to characterize the performance of the attachments and determine the optimal attachment design.

A wide range of component tests were conducted with different keyway bolt materials and shapes, nut configurations, and slot and keyway designs to optimize the performance of the cable-to-post attachment. The size and shape of the slot and keyway were developed and showed consisted release behavior for the keyway bolt. The keyway bolts were tested with C1018 and A449 steel. The A449 keyway bolt was selected as the optimum design which provided a lateral resistance above 8.00 kips (35.59 kN) while releasing the cable vertically at an average load of 1.18 kips (5.25 kN). A grade 8 high-topped nut was selected for the final design to provide adequate thread stripping resistance of the keyway bolt.

Cable barrier bogie tests were conducted to observe the behavior of the newly developed cable-to-post attachments relative to the curved keyway bracket connection design used in full-scale crash test nos. 4CMB-1 through 4CMB-3. The C1018 keyway bolts did not provide enough lateral resistance to achieve the desired post rotation angle of 33 degrees, which was determined from test no. HTCC-6 that utilized the curved keyway brackets to attach the cable to the posts. Two tests that utilized the A449 keyway bolt and grade 8 high-topped nut, test nos. HTCC-4 and HTCC-5, showed maximum post rotation angles of 34 and 24 degrees, respectively, and the behavior of the posts were similar to test no. HTCC-6.

Therefore, the A449 keyway bolt was considered an acceptable design replacement for the curved keyway bracket that performed well in test nos. 4CMB-1 and 4CMB-2. The keyway bolt cable-to-post attachments showed similar cable release behavior as the previous design and

the angle of the keyway bolt arm should preclude cable would snag on the keyway bolts. Further, the design of the keyway bolt should be much simpler and less expensive than the previously used curved keyway bracket design. Details and pictures of the recommended keyway bolt attachments are shown in Figure 150.

The following statements are applicable to the material described on the front of this Test Report:

1. Except as noted, the steel supplied for this order was melted, rolled and processed in the United States.
2. Mercury was not used during the manufacture of this product; nor was the steel contaminated with mercury during processing.
3. Unless directed by the customer, there are no welds in any of the coils produced for this order.
4. The laboratory that generated the analytical or test results can be identified by the following key:

Certificate Number	Lab Code	Laboratory		Address
0358-01	7388	**CSMD**	Charter Steel Melting Division	1658 Cold Springs Road, Saukville, WI 53080
0358-02	8171	**CSRD/ CSPD**	Charter Steel Rolling/ Processing Division	1658 Cold Springs Road, Saukville, WI 53080
0358-03	123633	**P4**	Charter Steel Ohio Processing Division	6255 US Highway 23, Risingsun, OH 43457
0358-04	125544	**CSC**	Charter Steel Cleveland	4300 E. 49th St., Cuyahoga Heights, OH 44125-1004
0358.05	128003	**CSDT**	Charter Steel Detroit	23860 Sherwood Ave. Center Line, MI 48015
*	*	--	Subcontracted test performed by laboratory not in Charter Steel system	

5. When run by a Charter Steel laboratory, the following tests were performed according to the latest revisions of the specifications listed below, as noted in the Charter Steel Laboratory Quality Manual:

Test	Possible Laboratory	Specification
Chemistry Analysis	CSMD, CSC	ASTM E415; ASTM E1019
X-ray Fluorescence Stainless and Alloy Steel	CSC	ASTM E572
Macroetch	CSMD, CSC	ASTM E381
Hardenability (Jominy)	CSMD, CSC	ASTM A255; SAE J406; JIS G0561
Grain Size	CSMD	ASTM E112
Tensile Test	CSRD/CSPD, P4, CSC, CSDT	ASTM E8; ASTM A370
Rockwell Hardness	CSMD, CSRD/CSPD, P4, CSC, CSDT	ASTM E18; ASTM A370
Microstructure (spheroidization)	CSRD/CSPD, P4	ASTM A892
Inclusion Content (Methods A, E)	CSRD/CSPD, CSC	ASTM E45

Charter Steel has been accredited to perform all of the above tests by the American Association for Laboratory Accreditation (A2LA). These accreditations expire 01/31/09

All other test results associated with a Charter Steel laboratory that appear on the front of this report, if any, were performed according to documented procedures developed by Charter Steel and are not accredited by A2LA.

6. The test results on the front of this report are the true values measured on the samples taken from the production lot. They do not apply to any other sample.
7. This test report cannot be reproduced or distributed except in full without the written permission of Charter Steel. The primary customer whose name and address appear on the front of this form may reproduce this test report, subject to the following restrictions:
   - It may be distributed only to their customers
   - Both sides of all pages must be reproduced in full
8. This certification is given subject to the terms and conditions of sale provided in Charter Steel's acknowledgment (designated by our Sales Order number) to the customer's purchase order. Both Order numbers appear on the front page of this Report.
9. Where the customer has provided a specification, the results on the front of this test report conform to that specification unless otherwise noted on this test report.

Mechanical Galv-Plating Corporation
Quality Plating & Galvanizing Services

Coating Certification:

Name: Amanda Bent Bolt Co.
1120 C.I.C. Drive
Logan, OH 43138

Date: 3/25/10
Invoice: 24341

This is to certify that Mechanical Galv-Plating Corporation has processed the following product:

Part No.: BUA25-UW-M
Quantity 556 pcs
Mfg. Lot No.: 1001561610
Plt. Lot No.: 310002
P.O. No.: OS89795

In Conformance with the requirements of:

Specification: Mechanically Galvanize ASTM B695 Class 55 Type I

Test Results:

Plating Thickness: .0022"

Remarks/Comments:

Note: This form is intended to be a specification certification only and is not to be construed as a warranty from Mechanical Galv-Plating Corporation.
