DEVELOPMENT OF AN ECONOMICAL GUARDRAIL SYSTEM FOR USE ON WIREFACED, MSE WALLS

Publication No. FHWA-CFL/TD-12-009

FEBRUARY 2012

CENTRAL FEDERAL LANDS HIGHWAY DIVISION 12300 WEST DAKOTA AVENUE Lakewood, CO 80228

FOREWORD

The Federal Lands Highway Division (FLHD) designs and constructs numerous wire-faced, mechanically-stabilized (MSE) walls across the U.S. These MSE walls are utilized to support highways and roadways built on sloped terrain which may carry significant vehicular traffic. The FLHD designs and constructs vehicular barrier systems which are placed within the exterior region of MSE walls. This report contains the research results aimed at the development of economical and crashworthy barrier systems for placement on top of and near the exterior edge of MSE walls.

The objective for this study was to develop an economical barrier system for safely treating vertical drop-offs located at the outside edge of wire-faced, MSE walls. The new barrier system was to be capable of providing acceptable safety performance during high-speed, high-energy passenger car impacts, be easily maintained, and not impart unreasonable damage to the MSE wall system and was to be evaluated according to the Test Level 3 (TL-3) safety performance criteria set forth in the American Association of State Highway and Transportation Officials (AASHTO) Manual for Assessing Safety Hardware (MASH).

The study included numerous design concepts, significant dynamic component testing to determine post type, length, and placement, and development of a non-blocked version of the MGS with steel posts placed at the slope break point of a 3H:1V fill slope. Full-scale crash testing was successfully used to evaluate the proposed design. TL-3 and TL-2 guidance was provided regarding the placement of a non-blocked, steel-post version of the MGS on wire-faced, MSE walls. The results from this study are recommended for use to update Central Federal Lands Highway Division's (CFLHD) Standard Detail C255-50, dated August 18, 2008, regarding semi-rigid barriers installed on welded, wire-face, MSE walls.

F. David Zanetell, P.E., Director of Project Delivery Federal Highway Administration Central Federal Lands Highway Division

MwRSF Research Report No. TRP-03-235-11

February 2012

UNCERTAINTY OF MEASUREMENT STATEMENT

The Midwest Roadside Safety Facility (MwRSF) has determined the uncertainty of measurements for several parameters involved in standard full-scale crash testing and non-standard testing of roadside safety features. Information regarding the uncertainty of measurements for critical parameters is available upon request by the sponsor and the Federal Highway Administration.

INDEPENDENT APPROVING AUTHORITY

The Independent Approving Authority (IAA) for the data contained herein was Mr. Scott Rosenbaugh.

EXECUTIVE SUMMARY

Wire-faced, mechanically-stabilized earth (MSE) walls provide an economical method for constructing vertical structures for supporting roadways where local topography or high land costs preclude the use of conventional fill slopes. While an economical solution for slope stability, MSE walls create safety issues by producing deep vertical drop-offs adjacent to the roadway. For years, the Federal Lands Highway Division (FLHD) has designed and constructed a large number of MSE walls across the United States (U.S.). The accepted practice has been to install the face of conventional, wood-post W-beam guardrail nearly 10 ft (3.0 m) away from the exterior face of an MSE wall, when considering 2 ft (0.6 m) of level surface behind the posts, an adjacent 3H:1V fill slope, and a 2-ft (0.6-m) fill height. Thus, it became desirable to place the barrier systems closer to the exterior edge of the MSE wall. Unfortunately, no methods were currently available for anchoring these barriers at or near the exterior face.

The primary research objective for this study was to develop an economical barrier system for safely treating vertical drop-offs located at the outside edge of wire-faced, MSE walls. During high-speed, high-energy impacts with passenger vehicles, the new barrier system should not impart unreasonable damage to the MSE wall system. The new barrier system should be easily maintained without requiring extensive repairs to the MSE wall structure. Several design concepts were considered for a new barrier system positioned closer to the exterior edge of wire-faced, MSE walls. The standard MGS along with its design variations were also considered. The new or modified barrier system was to be evaluated according to the Test Level 3 (TL-3) safety performance criteria set forth in the American Association of State Highway and Transportation Officials (AASHTO) Manual for Assessing Safety Hardware (MASH).

For this study, the Midwest Guardrail System (MGS) was extensively reviewed and considered for use in shielding the vertical drop-offs associated for MSE walls. From a review, the MGS was shown to provide acceptable safety performance when used for shielding wide, transverse culvert structures as well as fill slopes as steep as 2H:1V.

Multiple design concepts were considered for treating vertical drop-offs at the exterior face of wire-faced, MSE wall. As part of the brainstorming and selection process, several factors were considered, including: (1) control of overall project costs; (2) environmental impacts; (3) use of an economical barrier system; (4) concerns for MSE wall damage; (5) use 3H:1V fill slope at the top outer edge of MSE wall; (6) use of beam and post barriers for aesthetics; (7) constructability, maintenance, and repair of barrier system; and (8) approximate dynamic deflection and assumed vehicle trajectory for high-speed, high-energy vehicular impacts into semi-rigid guardrail systems. After considering concerns for constructability and repair, those barrier systems with deeply-embedded reinforced concrete foundations in combination with tension elements were eliminated from further investigation and comparison. Later, five design concepts were subjected to a basic cost analysis and system comparison. Following this effort, the project team chose to further develop a non-blocked version of the MGS with the posts placed at the slope break point of a 3H:1V fill slope.

Dynamic component testing was utilized to determine the post-soil behavior of steel and wood posts embedded in compacted, soil materials used for constructing wire-faced, MSE walls as

well as to evaluate the effects of sloped terrain and different installation methods. Twenty-six dynamic tests were performed to evaluate the propensity for MSE wall damage, select post length, and determine post material and section. Following the post testing program, a non-blocked version of the MGS was recommended for evaluation within a crash testing program using: (1) steel W-beam backup plates; (2) 6-ft (1.8-m) long posts manufactured from either W6x8.5 (W152x12.6) or W6x9 (W152x13.4) steel sections; (3) posts driven at the slope break point of a 3H:1V fill slope adjacent to and on top of a wire-faced, MSE wall; and (4) posts installed using a 40-in. (1,016-mm) embedment depth. All other MGS features were maintained, including, rail splices at mid-span locations, 31-in. (787-mm) top mounting height, and 75-in. (1,905-mm) post spacing.

A full-size, MGS and MSE wall system was constructed for testing and evaluation. The non-blocked MGS was constructed with the back side of the steel posts positioned approximately 2 ft – 9 in. (0.84 m) away from the inside edge of the wall facing fill or 5 ft – 9 in. (1.75 m) away from the outer edge of the wire-faced, MSE wall. The modified MGS system was crash tested successfully using the 1100C small car and 2270P pickup truck vehicles according to the Test Level 3 (TL-3) safety performance guidelines provided in MASH. In both crash tests, no damage was observed in the MSE wall system. As a result of the extensive dynamic component testing and full-scale vehicle crash testing programs, the non-blocked MGS was recommended for use with wire-faced, MSE walls when placed at the slope break point of a 3H:1V fill slope. The modified MGS reduces the required width of the MSE wall, thus resulting in decreased construction costs.

For this research study, the test results and findings are contained in two different reports. The first report contains the design review of the MGS, design considerations, a summary of the dynamic component testing program, details for the MGS and MSE wall systems, the MASH full-scale crash testing requirements, results from the two full-scale crash tests, as well as a project summary, overall conclusions, and recommendations. This report (TRP-03-235-11) is entitled, "Development of an Economical Guardrail System for Use on Wire-Faced, MSE Walls." The second report contains the procedures utilized for the dynamic bogic testing program, results from the 26 dynamic post tests, as well as a post testing summary with conclusions and recommendations specific to the component testing program. This report (TRP-03-231-11) is entitled, "Investigation and Dynamic Component Testing of Wood and Steel Posts for MGS on a Wire-Faced, MSE Wall."

Following the completion of the research program noted above, MwRSF researchers also determined the minimum lateral barrier offset for wire-faced MSE wall systems which utilize a 3H:1V fill slope. For non-blocked MGS systems, the back side of steel posts are recommended to be placed a minimum of 1 ft (0.30 m) away from the inside edge of the wall facing fill or 4 ft (1.22 m) away from the outer edge of the MSE wall, whichever results in the largest lateral offset between the post and exterior wall face. For this recommendation, the minimum lateral offset between the rail face and outer edge of the MSE wall would be 4 ft $-9 \frac{1}{4}$ in. (1.45 m). For varying thickness of select wall backfill and different widths for the 3H:1V fill slope, three different configurations were prepared to demonstrate the recommended guidance regarding the minimum lateral offset for the steel posts, as shown in Figures ES-1 through ES-3. This design guidance is suitable for use under both TL-2 and TL-3 roadside applications.

Figure ES-2. Schematic. Non-Blocked, Steel-Post MGS Centered at Slope Break Point with Minimum Lateral Offset.

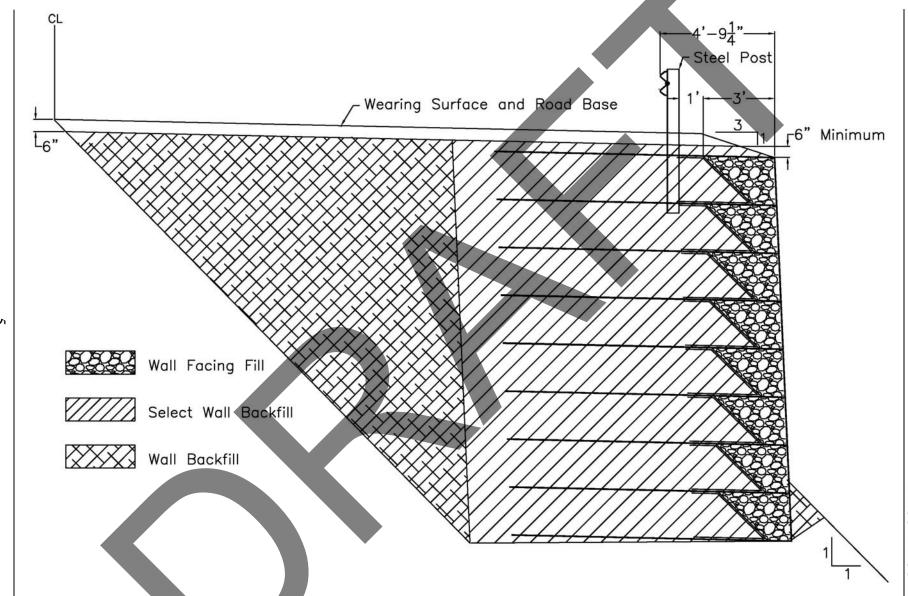

Figure ES-3. Schematic. Non-Blocked, Steel-Post MGS with Minimum Lateral Offset.

CHAPTER 1. INTRODUCTION

1.1 BACKGROUND

Wire-faced, mechanically-stabilized earth (MSE) walls provide an economical method for constructing nearly vertical walls adjacent to roadways where the local topography or the high cost of land precludes the use of conventional fill slopes. These MSE walls incorporate wire-mesh layers, cages, or baskets for surrounding and containing the angular aggregate or larger stones. The sequential placement of these layers or cages allow for a nearly vertical surface to be formed at the outside edge of the structure. While an economical solution for slope stability, MSE walls create safety issues by producing deep vertical drop-offs adjacent to the roadway that require the installation of a barrier system.

The Federal Lands Highway Division (FLHD) of the Federal Highway Administration (FHWA) designs and constructs a large number of wire-faced, MSE walls throughout the United States (U.S.). Within the Central Federal Lands Highway Division (CFLHD), Standard Detail C255-50 dated August 18, 2008 provides significant information regarding the general configuration of welded wire face MSE walls, as shown in Figures 1 and 2^[1]. According to the CFLHD details, MSE wall systems are constructed using multiple layers of rock and reinforcing elements vertically placed on top of one another. The outer vertical edge consists of a special compaction zone of wall facing fill measuring approximately 3 ft (0.91 m) wide. The maximum layer height of compacted fill material is 2 ft (0.61 m) between the horizontal reinforcement elements. Above the last reinforcement element, the MSE wall system contains one additional layer of select wall backfill. The top layer of select wall backfill ranges in thickness from 6 in. (0.15 m) to 20 in. (0.51 m), but it is 1 ft (0.30 m) thick in "normal" configurations. Subsequently, a combined layer of road base material and wearing surface covers the top of the MSE wall system. However, CFLHD's C255-50 detail does not specify a range in thickness for the combined layer of road base material and wearing surface.

According to Standard Detail C255.50, CFLHD's accepted practice is to install conventional, wood-post W-beam guardrail 2 ft (0.61 m) laterally away from the slope break point (SBP), as measured to the backside of the wood posts. For this configuration, wood guardrail posts utilize a minimum embedment depth of 5 ft (1.52 m), as measured from the post base to the top of the select wall backfill material. For a 1-ft (0.30-m) thick layer of road base and wearing surface, the total embedment depth for wood posts could easily reach 6 ft (1.83 m), thus resulting in post lengths of 8 ft (2.44 m) or more. Depending on the size and grade of a wood post, concerns may exist for premature post fracture in standard W-beam guardrail systems configured with a 6-ft (1.83-m) embedment depth. Premature wood post fracture may potentially compromise the safety performance of wood-post, W-beam guardrail systems.

Using a "normal" 1-ft (0.30-m) thick top layer of select wall backfill and a 3-ft (0.91 m) wide special compaction zone of select wall facing fill, the soil terrain at the outer top region of the MSE wall would conform to a 3H:1V fill slope. Assuming a 1 ft (0.30 m) thick layer of road base and wearing surface above the top layer of select wall backfill in combination with a 3H:1V fill slope, the slope break point would occur approximately 6 ft (1.83 m) laterally away from the outer vertical edge of the MSE wall system. Therefore, a typical roadside cross section could be

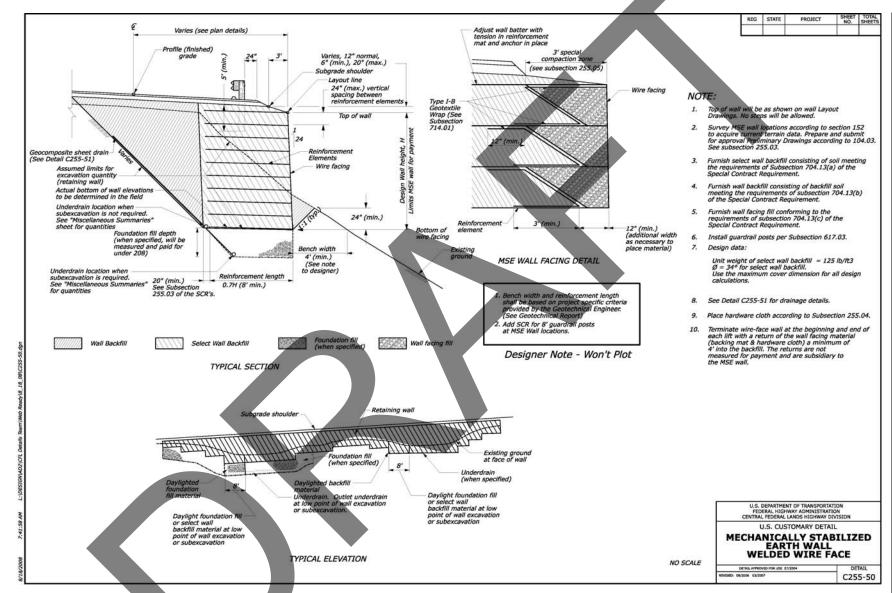

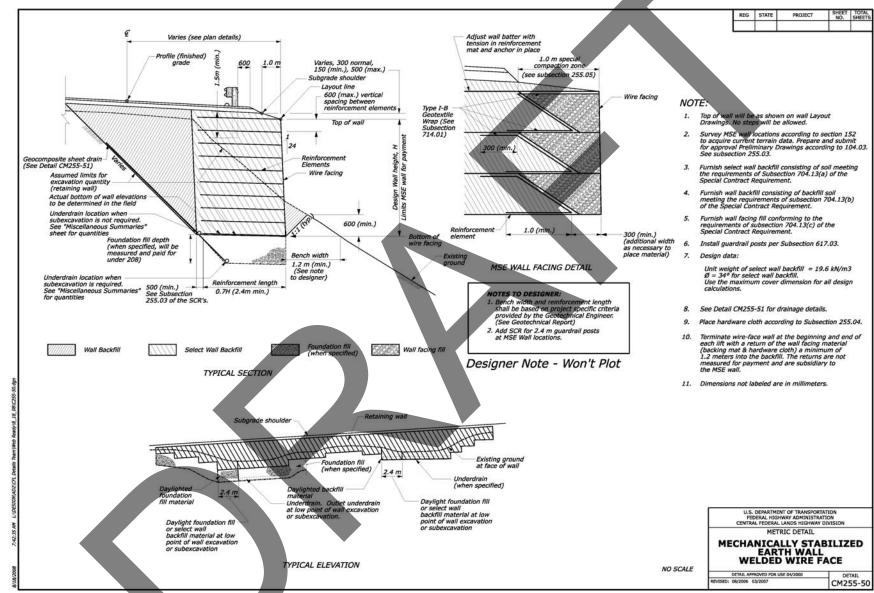

Figure 1. Schematic. CFLHD's Standard Detail C255-50.

9

Figure 2. Schematic. CFLHD's Standard Detail C255-50. (continued.)

configured with 2-ft (0.61-m) wide level terrain behind the guardrail posts and a 6-ft (1.83-m) wide 3H:1V fill slope extending to the vertical edge of the MSE wall system. The fill slope would contain 2 ft (0.61 m) of road base, wearing surface, and top layer of select wall backfill. Using this common configuration, CFLHD's accepted practice would result in a guardrail system being installed 8 ft (2.44 m) away from the exterior face of the MSE wall, as measured to the backside of the wood posts. Typically, wood-post, W-beam guardrail systems are configured with 6-in. x 8-in. (152-mm x 203-mm) posts and offset blocks in combination with a 3½-in. (83-mm) deep rail section. For this common roadside configuration, the front face of the W-beam rail would be 9 ft - 7½ in. (2.93 m) laterally away from the exterior vertical face of the MSE wall, as shown in Figure 3. Large lateral barrier offsets will increase the cost of the MSE wall structure and potentially result in additional environmental impacts on FLHD projects.

Unfortunately, methods for anchoring crashworthy barrier systems at or near the outside face of a wire-faced, MSE wall were unavailable. As a result, there existed a need to develop an economical barrier system that would either reduce the large lateral barrier offset to or near 0 ft (0 m) when placing low-cost standard W-beam guardrails on wire-faced MSE walls or decrease the overall width of the MSE wall structure. In addition, the development of an economical barrier system would possibly help to define or clarify the minimum lateral offset between the barrier and the outer edge of the MSE wall system.

W-beam guardrail systems are normally used to prevent motorists from striking serious hazards adjacent to low- and medium-service level highways. During design impact event, these barriers rely on energy dissipation associated with the rotation of guardrail posts in soil and incur significant dynamic deflections. The economics of wire-faced, MSE wall construction would dictate minimizing the lateral width required for the shoulder, guardrail system, and soil fill placed behind the guardrail. Additionally, the tradeoff between damage incurred to the wire-faced, MSE wall during a vehicular impact event and the initial cost of construction is an important consideration.

A design of a cantilevered, W-beam barrier system was submitted to the Midwest Roadside Safety Facility (MwRSF) project team for review. This modified barrier system was configured for attachment to the exterior vertical surface of wire-faced, MSE walls and incorporated long, exterior-mounted, vertical posts and/or rigid sleeves for anchoring guardrail posts, as well as costly foundation hardware placed within the MSE wall, such as long steel anchor rods, plates, and reinforced concrete beams. Unfortunately, this unique barrier and anchorage system, along with other similar systems, have not been previously crash tested and evaluated according to impact safety standards. It is our opinion that an exterior-mounted, crashworthy barrier system would likely be very expensive to construct and difficult to maintain and repair when considering the structural elements that are embedded deep into the MSE wall. The connection between the foundation and barrier system would have required tension elements at fairly close spacing, such as at 6 ft - 3 in. (1.90 m) centers. For this configuration, it would be extremely cumbersome to construct the MSW wall system when placing and compacting the select wall backfill material around the tension elements. Secondarily, repair of these types of barrier systems would be impractical. In addition, these systems would likely result in greater concerns for damage to the MSE wall structure during vehicular impact events.

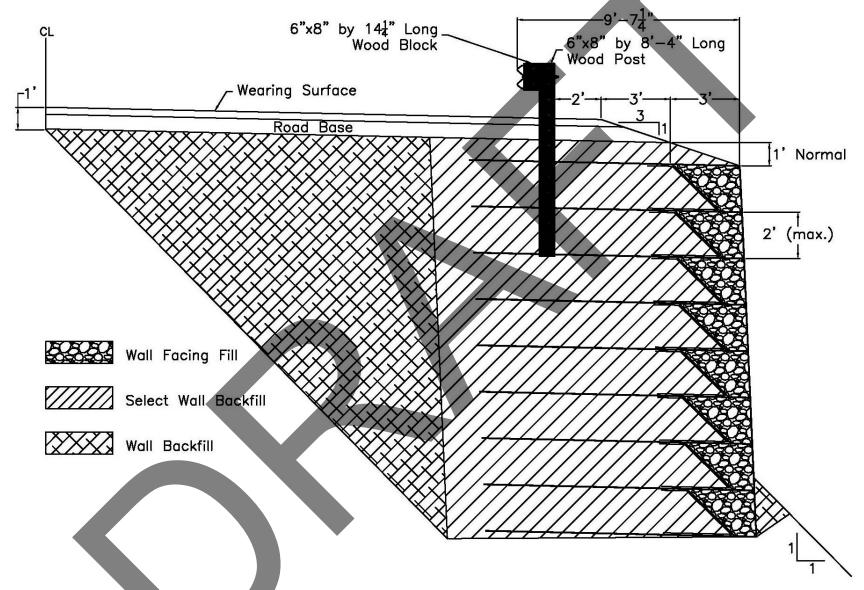

Figure 3. Schematic. Baseline Configuration for W-Beam Guardrail and MSE Wall.

Full-scale crash testing of strong-post, W-beam guardrails installed in rigid foundations, such as solid rock, asphalt pavements, and concrete mow strips, has shown that preventing the posts from absorbing energy by rotating in the soil severely limits the barrier's ability to contain and redirect large passenger vehicles, such as light trucks and sport utility vehicles (SUVs).^[2,3] Therefore, the optimum barrier system would minimize damage to the wire-faced, MSE wall structure and decrease the required lateral offset between the guardrail face and the outside vertical edge of the wall system.

In recent years, the Midwest Guardrail System (MGS) has demonstrated improved vehicle containment, safety performance, and redirective capacity over that provided by conventional, strong-post, W-beam guardrail systems. [See references 4-13.] The MGS utilizes mid-span guardrail splices, an increased top rail mounting height of 31 in. (787 mm), an increased blockout depth of 12 in. (305 mm), and a reduced post embedment of 40 in. (1,016 mm). From the seemingly simple design changes, the redirective capacity of the MGS has proven to be more than double that provided by standard W-beam guardrail systems. [See references 4-13.] The MGS has also been shown to provide satisfactory safety performance when used in combination with curbs, culverts, slopes, and other roadside anomalies. Thus, the standard MGS, its existing variations, as well as any potential design modifications, were also considered for use in shielding the hazardous, vertical drop-offs created by the construction of wire-faced, MSE walls.

1.2 OBJECTIVE

The primary research objective was to develop an economical barrier system for safely treating vertical drop-offs located at the outside edge of wire-faced, MSE wall systems. During high-speed, high-energy impacts with passenger vehicles, the new barrier system should not impart unreasonable damage to the MSE wall system when positioned at the minimum lateral offset between the post and edge of the MSE wall system. The new barrier system should be easily maintained without requiring extensive repairs to the MSE wall structure. Several design concepts were to be considered for a new barrier system that was positioned closer to the exterior edge of wire-faced, MSE walls. In addition, the standard MGS along with its design variations were to be considered for use or modification. The new or modified barrier system was to be evaluated according to the Test Level 3 (TL-3) safety performance criteria set forth in the American Association of State Highway and Transportation Officials (AASHTO) *Manual for Assessing Safety Hardware* (MASH). Design guidance for TL-2 impact conditions will also be available in the final recommendations.

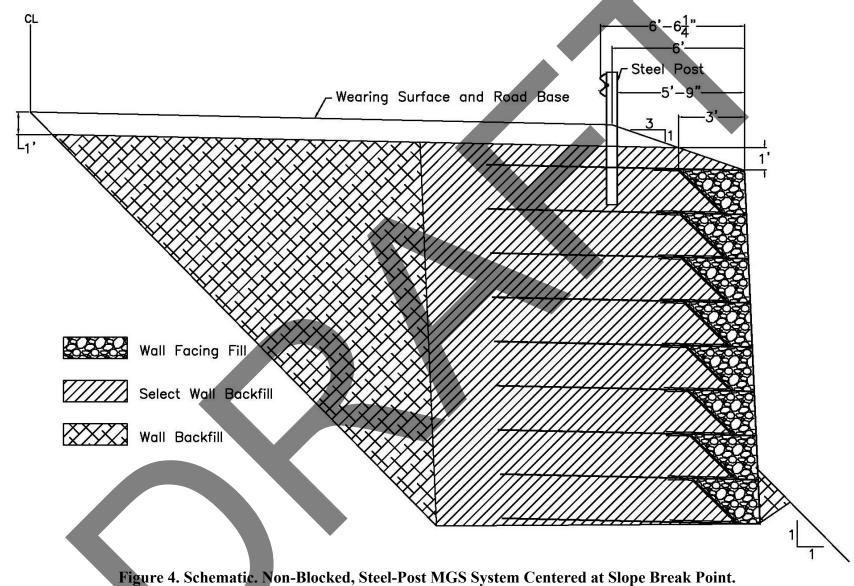

1.3 SCOPE

The research objectives were achieved through the completion of multiple tasks within the research and development effort. First, a design review, comparisons, and evaluations were performed on various barrier concepts and systems. Dynamic component testing was then utilized to determine the post-soil behavior of steel and wood posts placed in compacted soil material representative of that typically used for the construction of wire-faced, MSE walls. This post testing program was also used to evaluate the propensity for damage to the MSE wall system, select the appropriate post length, and determine the post material type. After considering various barrier concepts, the standard MGS was modified by removing the 12-in.

(305-mm) deep wood spacer blocks and by incorporating steel W-beam backup plates. Subsequently, the modified barrier system was installed at the slope break point of a 3H:1V fill slope using a 6-ft (1.8 m) lateral offset between the steel post's centerline and the outer edge of the MSE wall as shown in Figure 4. The modified MGS was crash tested and evaluated according to the TL-3 safety performance guidelines provided in MASH using 1100C small car and 2270P pickup truck vehicles striking at a target impact speed of 62 mph (100 km/h) and a target impact angle of 25 degrees. Finally, conclusions and recommendations were made that pertained to the safety performance of the non-blocked, MGS installed on top of a wire-faced, MSE wall system.

CHAPTER 2. REVIEW OF MIDWEST GUARDRAIL SYSTEM (MGS)

The MGS has demonstrated excellent safety performance when modified for use in treating hazardous terrain. More specifically, full-scale crash testing has demonstrated that the MGS can successfully contain and redirect heavy passenger vehicles when placed in close proximity to both vertical drop-offs adjacent culverts headwalls and 2H:1V fill slopes. [See references 15-18.]

First, the MGS was adapted to span across concrete box culverts measuring 24-ft (7.3 m) wide or less, as measured parallel to the roadway. The long-span MGS system utilized three timber breakaway CRT posts, measuring 6 in. (152 mm) wide by 8 in. (203 mm) deep by 6 ft (1,829 mm) long and spaced on 6 ft - 3 in. (1,905 mm) centers, both on the upstream and downstream ends of the culvert system. During the crash testing program, the MGS contained a 2270P pickup truck even after allowing it to extend approximately 3 ft (0.9 m) beyond the edge of the vertical drop off and later redirected it back onto the traveled-way without serious risk to the occupants.

The MGS was also modified to allow for post placement at the slope break point of a 2H:1V fill slope. This MGS design variation incorporated W6x9 (W152x13.4) steel posts measuring 9 ft (2.7 m) long and spaced on 6 ft – 3 in. (1,905 mm) centers. For this study, the modified MGS safely contained and redirected a 2270P pickup truck even when a maximum dynamic barrier deflection of 57.6 in. (1,463 mm) was observed.

Both MGS design variations were successfully crash tested and evaluated according to the TL-3 safety performance guidelines provided in MASH. Based on these results, the research team believed that the MGS should be considered for modification and use on top of or near the outer edge of wire-faced, MSE walls.

CHAPTER 3. DESIGN CONSIDERATIONS

Multiple design concepts were considered for use in treating vertical drop-offs created with the construction of wire-faced, MSE wall systems. As part of the brainstorming and selection process, several factors were considered, including: (1) control of overall project costs through a reduction in the lateral offset used for placing barrier systems or a decrease in the overall width of the MSE wall structure; (2) environmental impacts on FLHD projects, such as increased excavation into mountainous terrain or increased structure encroachment into nearby streams and forests; (3) use of an economical barrier system; (4) concerns for damage to the wire-faced, MSE wall structure; (5) MwRSF and CFLHD personnel agreed that placement of a 3H:1V fill slope at the top outer edge of MSE wall structure could be reasonably maintained, should not easily erode, and should form basis of analysis for most barrier concepts; (6) use of beam and post barriers either possessing flexibility to address aesthetics or providing openness for enhanced visualization of surroundings; (7) constructability, maintenance, and repair of the new barrier system; and (8) approximate dynamic deflection and assumed trajectory for high-speed, high-energy vehicular impacts into semi-rigid guardrail systems.

Early in the study, CFLHD personnel and vendors of MSE wall systems provided various concepts for placing W-beam guardrail systems on top of or at the outer vertical edge of the MSE walls. These barrier designs used rigid steel sleeves for anchoring guardrail posts, which may have reduced concerns for inflicting significant damage to wire-faced, MSE wall systems near the outer edge. These barrier designs often utilized costly foundation hardware, including the use of long steel anchor rods and plates as well as reinforced concrete foundations. Unfortunately, the crashworthiness of exterior-mounted, barrier and anchorage systems have not been verified through full-scale vehicle crash testing programs.

Using the FLHD and MSE wall vendor details, MwRSF prepared two simple barrier concepts for consideration and discussion, as shown in Figures 5 and 6. For these design concepts, long tension elements in combination with deeply-embedded reinforced concrete foundations would be required to restrain the posts and/or supporting rigid sleeves. In addition, the spacing of the long tension elements would be fairly close, or assumed to occur at 6 ft – 3 in. (1,90 m) centers. Unfortunately and for these design concepts, the research team believed that it would be difficult to construct the MSE wall structure while compacting fill around the long, sloped tension elements, one or two per post location. In addition, it was deemed impractical to repair any damaged tension elements or reinforced concrete foundations within the MSE wall structure in the event that damage occurred. After considering concerns for constructability and repair, barrier concepts with deeply-embedded reinforced concrete foundations in combination with long, sloped tension elements were eliminated from further investigation and comparison.

As noted previously, MwRSF prepared a baseline barrier configuration for use on top wire-faced MSE walls using CFLHD's accepted practice. For this baseline configuration, a wood-post, Wbeam guardrail system was installed 8 ft (2.44 m) away from the exterior face of the MSE wall, as shown in Figure 3. Recall, this barrier system was configured with 6-in. x 8-in. (152-mm x 203-mm) wood posts and offset blocks in combination with a 3½-in. (83-mm) deep rail section, thus positioning the rail face 9 ft - 7½ in. (2.93 m) laterally away from the exterior edge of the MSE wall.

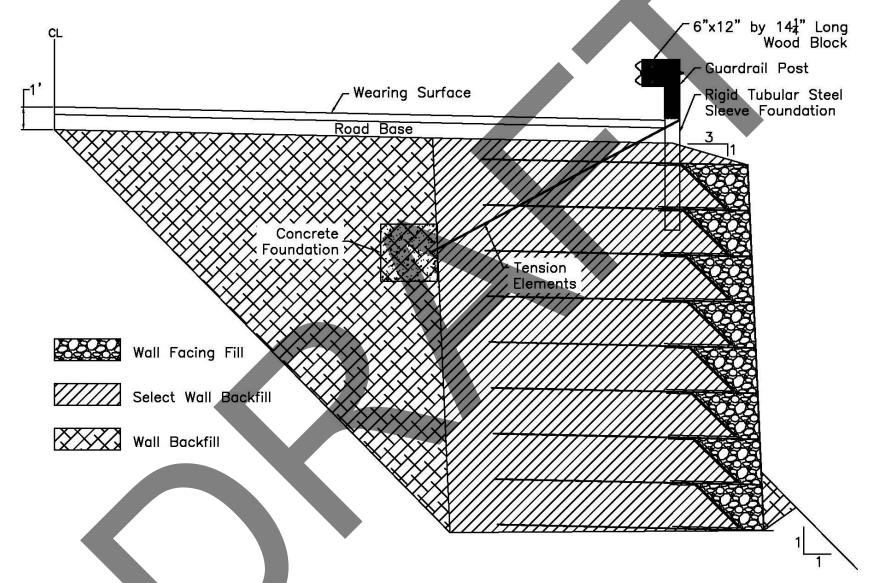

Figure 5. Schematic. MGS System with Rigid Sleeve, Concrete Foundation, and Tension Elements.

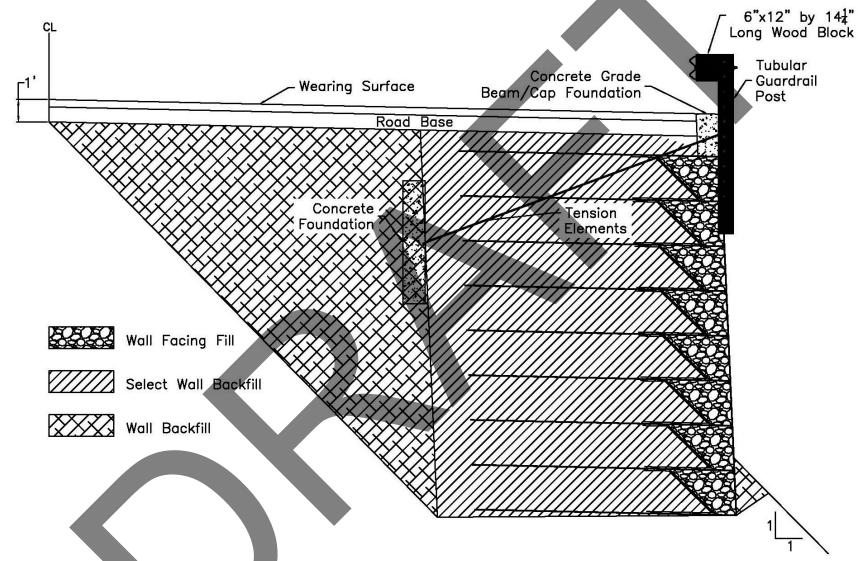

Figure 6. Schematic. MGS System with Tubular Post, Concrete Foundations, and Tension Elements.

Using the design factors noted above, five additional barrier concepts were prepared for consideration and discussion. Later, these barrier concepts were compared to one another using a basic, incremental-cost analysis, which considered differences in system components and varied widths of MSE wall.

Four initial barrier concepts were configured using features from the MGS. Concept no. 1 consisted of a standard MGS located 24 in. (610 mm) forward from the slope break point (SBP), as measured to back of the steel post, as shown in Figure 7. This concept was very similar to the baseline barrier configuration depicted in Figure 3. However, Concept No. 1 incorporated the MGS features, a steel post in lieu of a wood post, and a 12-in. (302-mm) versus 8-in. (203-mm) deep wood offset block. As a result, Concept No. 1 became the modified baseline configuration for use in the basic incremental-cost analysis. Concept no. 2, as depicted in Figure 8, consisted of a non-blocked MGS located 24 in. (610 mm) forward from the slope break point, as measured to back of steel post. A standard MGS with the steel post centered at the slope break point was selected for Concept no. 3, as shown in Figure 9. Finally, Concept no. 4 utilized a non-blocked MGS with the steel post centered at the slope break point, as depicted in Figure 10

One additional barrier concept was proposed which did not utilize the approximately 6-ft (1.8-m) wide, 3H:1V fill slope. Instead, the final barrier concept utilized a heavily-reinforced concrete slab and grade beam system that was placed on a mostly level surface. As depicted in Figure 11, Concept no. 5 incorporated an aesthetic, glue-laminated (glulam) timber rail and post system which was placed at the top exterior edge of the wire-faced, MSE wall system using steel mounting brackets which attached to the concrete slab and grade beam.

Subsequently, the five barrier concepts were compared using relative reductions in the required width of the MSE wall structure as the primary metric along with reductions in the cost of the wire-faced, MSE wall structure as a function of width and changes in the installation cost for the various barrier systems. Concept no. 1 served as the basis for comparison; since, the barrier face was farthest from the outside edge of the MSE wall structure and required the greatest structure width.

A comparison of the five barrier concepts is shown in Table 1. From this information, an incremental decrease in the required width of MSE wall structure was observed with the progression of Concept nos. 1 through 5. The cost analysis was based on the assumption that (1) the MSE wall was placed on a 1H:1V fill slope and (2) each 1ft (0.3 m) reduction in lateral barrier offset would result in a 1 ft (0.3 m) reduction in the height of the MSE wall. CFLHD personnel provided a cost for the MSE wall to be approximately \$50/ft². When considering a 1-ft (0.3-m) height reduction, a net cost reduction of \$50 per linear ft of MSE wall was used in the analysis. For example, Concept no. 2 provides a 1 ft (0.3 m) reduction in wall width as compared to Concept no. 1 due to the elimination of the 12-in. (305- mm) deep timber spacer blocks. Thus, the front face of the barrier is placed 1 ft (0.3 m) closer to the outside edge of the MSE wall system and results in a cost reduction of \$52/ft. When compared to Concept no. 1, the greatest cost reduction for the MSE wall structure was determined as \$450/ft for Concept no. 5.

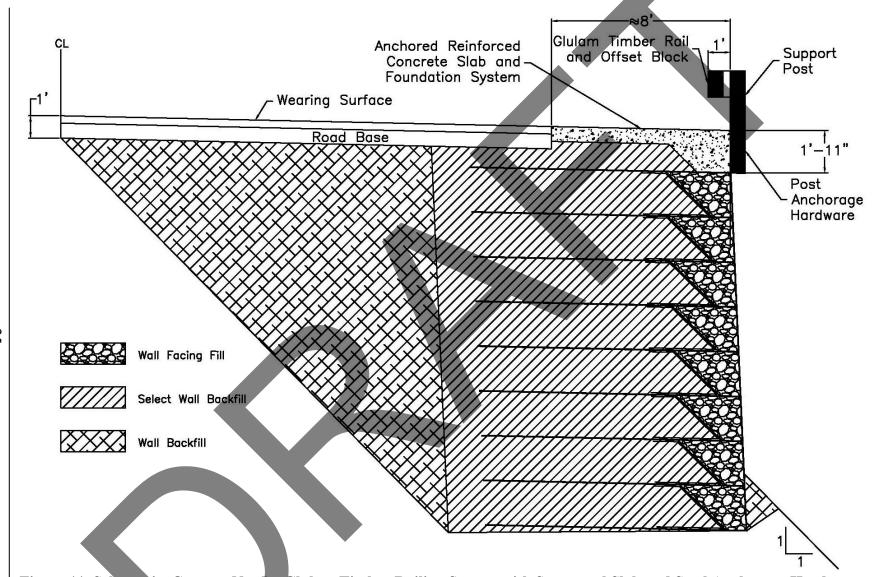

Figure 11. Schematic. Concept No. 5 – Glulam Timber Railing System with Structural Slab and Steel Anchorage Hardware.

Table 1. Comparison of Barrier Concepts for Use on Wire-Faced, MSE Wall System.

		Reduction	Reduction	Reduction	Net Cost
Concept	System	Wall	Wall Cost	Barrier Cost	Reduction
No.	Description	Width (ft)	(\$/linear ft)	(\$/linear ft)	(\$/ft)
	Standard MGS - Steel Post				
1	- 2 ft from SBP to Back of Post	NA	NA	NA	NA
	- 6 ft Post Length				
	Non-Blocked MGS - Steel Post				
2	- 2 ft from SBP to Back of Post	1 ft	\$50/ft	\$2/ft	\$52/ft
	- 6 ft Post Length				
	Standard MGS - Steel Post				
3	- Post Centered at SBP	2.25 ft	\$112/ft	(\$8/ft)	\$104/ft
	- Est. 7 to 8 ft Post Length				
	Non-Blocked MGS - Steel Post				
4	- Post Centered at SBP	3.25 ft	\$162/ft	(\$4/ft)	\$158/ft
	- Est. 7 to 8 ft Post Length				
5	Glulam Timber Rail and Post	0.6	\$450/ft	(\$900/f4)	(\$250/f4)
3	- 1 ft from Rail Face to Edge	9 ft	\$430/N	(\$800/ft)	(\$350/ft)

When the costs of barrier construction were evaluated, only one barrier concept (Concept no. 2) was found to be more economical than a standard MGS guardrail. The net cost reduction for this concept was found to be less than \$2/ft and occurred due to the removal of the timber spacer blocks, the use of a shorter guardrail bolt, and the addition of a steel backup plate. Concept nos. 3 and 4 were estimated to be more costly than Concept no. 1 as a result of the anticipated need to increase post length near the 3H:1V fill slope. Concept no. 5 provided the greatest increase in barrier costs, \$800/ft, as compared to Concept no. 1. This large increase resulted from the high material and labor costs associated with the construction of a side-mounted, glulam timber beam and post system with attachment to the heavily-reinforced, concrete slab and grade beam system.

Barrier costs and savings in MSE wall construction were combined to produce a net reduction in construction costs for each option. Each of the MGS barrier alternatives (Concept nos. 2 through 4) provided a net cost reduction for the MSE wall and barrier systems when compared to the baseline condition of Concept no. 1. For example, Concept no. 4 (i.e., non-blocked MGS with steel posts placed at the slope break point) provided the greatest net cost reduction of \$158/ft when compared to the baseline configuration. Alternatively, the glulam timber beam and post configuration (Concept no. 5) actually produced a net cost increase when compared to baseline configuration (Concept no. 1). Based on the cost analysis and system comparison, the CFLHD-MwRSF project team selected Concept no. 4 for further development and use on wire-faced, MSE walls.

CHAPTER 4. BARRIER DESIGN ISSUES

The implementation of Concept no. 4 for use with a wire-faced, MSE wall system presents three potential problems, including: (1) failure of the rail to release from the posts; (2) rail rupture arising from contact with a post flange; and (3) overly stiff guardrail posts.

If a guardrail fails to release from a post, the rail element can be pulled down when the post rotates in the soil. In extreme cases, the rail will become disengaged from the vehicle and allow it to override the barrier. Standard MGS systems incorporate a button head post bolt and a wood spacer block. The small button head is more easily pulled through the post bolt slot, and the soft wood behind the rail eliminates the risk of the rail becoming pinched between the bolt head and the post flange. Elimination of the blockout could allow the rail to be pinched which would alter rail release characteristics. Further, removing the blockout and placing the posts in very stiff soil such as in a MSE wall system, would be expected to change the nature of post deformation during an impact. The stiffened post would not deflect in advance of the impacting vehicle. Thus, the stiff post would be more likely to be contacted by the front wheel and pushed down parallel to the rail. In this situation, the post bolt could be pushed parallel to the rail without generating a significant pull-out force.

The post bolt pullout problem was examined using first principles. Initially, the size of the shoulder on a standard post bolt was examined to determine if the rail element could actually become tightly pinched between the bolt head and the post flange. This dimensional analysis showed that a single layer of guardrail could not become tightly pinched and thus, a standard post bolt with an underside lug could possibly be used with the MGS without blocks.

The second post bolt pull-out issue that was investigated related to the potential motion of the post parallel to the rail. In this situation, the post bolt would quickly reach the end of the slot in the rail. In this loading condition, the post bolt would need to begin to tear out the end of the slot in order to release the rail from the post. The shear force required to yield the region of the guardrail in contact with the side of the bolt was calculated using the bolt bearing equation shown below:

$$F_v = (\sigma_w)(t_w)(D_b) = 3,400 \text{ lb } (15.1 \text{ kN})$$

where $\sigma_w = \text{yield strength of W-beam rail} = 50 \text{ ksi}$
 $t_w = \text{thickness of W-beam rail} = 0.109 \text{ in.}$
 $D_b = \text{bolt diameter} = 0.625 \text{ in.}$

After the W-beam begins to yield, it will initially begin to buckle, which would produce out-of-plane tearing in the guardrail. A great number of out-of-plane tearing tests were conducted during development of the BEST guardrail end terminal. [See references 19-21.] The BEST impact head causes out-of-plane tearing to cut a W-beam guardrail into four longitudinal strips. Static compression tests with the W-beam rail pushed over the hardened cutters demonstrated that out-of-plane tearing forces were generally below the estimated bearing yield force shown above. Never-the-less, a 25 percent dynamic load factor was applied to the bearing force to produce a tear-out force estimate of 4,200 lb (18.7 kN).

The post was modeled as a cantilever with a 4,200-lb (18.7-kN) resistive force at the top and a tire impact load applied 16 in. (406 mm) above the ground. This load condition was found to produce a plastic moment at the base of the post when the tire load approached 13,000 lb (57.8 kN). This loading would produce approximately 5.5 g's on the MASH 1100C test vehicle. Note that this acceleration is only slightly higher than those experienced on some roller coasters. Hence, the force required to reduce bolt tear out along the rail should not produce unsafe decelerations, even for impacts with an 1100C small car vehicle.

The concern about tearing of the guardrail when it contacted a post flange was resolved by reviewing prior crash test findings. Historical testing has shown that small cuts can be produced in a W-beam guardrail when it becomes trapped between the edge of a post flange and an impacting vehicle. The traditional solution to this problem has been to incorporate plates to prevent the rail from directly contacting a post. This inexpensive solution was incorporated into the new barrier

The final concern was that excessively stiff guardrail posts would not absorb enough energy and thereby lead to rail rupture. Note that guardrail posts were expected to be significantly stiffer because the posts were driven into a well-compacted, crushed limestone soil material adjacent to the baskets of large rocks and with the bottoms of the posts penetrating into the wire-mesh layers of compacted, crushed limestone. The large rocks inside the wire baskets were essentially constrained from any significant movement. Thus, the base of the posts adjacent to the baskets of rocks and penetrating into the wire-mesh layers would likely be constrained against lateral movement and rotation, thus potentially resulting in premature lateral torsional buckling and reduced energy dissipation. In order to investigate the post stiffness when installed in a MSE wall system, a series of dynamic bogie tests were conducted to determine the appropriate guardrail post length to support the guardrail and prevent damage to the MSE wall system. As summarized below, these dynamic post tests in the MSE wall produced high soil resistance, but the posts did not fail in lateral torsional buckling.

CHAPTER 5. DYNAMIC COMPONENT TESTING

5.1 OVERVIEW

Dynamic component testing was utilized to determine the post-soil behavior of steel and wood posts placed in compacted, soil material representative of that used for constructing wire-faced, MSE walls. This post testing program was also used to: (1) investigate the dynamic response of posts placed on 3H:1V fill slopes using alternative post installation methods; (2) evaluate the propensity for rotating posts to inflict damage to the MSE wall system; (3) select the appropriate post length ranging between 6 and 9 ft (1.8 and 2.7 m); and (4) evaluate common guardrail post sections, including 6-in. x 8-in. (152-mm x 203-mm) wood posts as well as W6x9 (W152x13.4) and W6x8.5 (W152 x 12.6) steel sections. Further details can be found in a MwRSF research report, entitled *Investigation and Dynamic Testing of Wood and Steel Posts for MGS on a Wire-Faced, MSE Wall.* [23]

A total of twenty-six dynamic tests were conducted during four rounds of testing on 6-in. x 8-in. (152-mm x 203-mm) wood posts, W6x16 (W152x23.8) steel posts, W6x9 (W152x13.4) steel posts, and W6x8.5 (W152 x 12.6) steel posts of multiple lengths and soil embedment depths. The posts were impacted $24\frac{7}{8}$ in. (632 mm) above the ground line.

For each bogie test, raw acceleration data was acquired and filtered, and then force vs. displacement and energy vs. displacement graphs were plotted. From the energy vs. displacement graphs, the average post-soil forces were calculated for displacements of 15 and 20 in. (381 and 508 mm) at the center rail height. Different soil gradations, terrain (i.e., level or sloped fill), installation methods, and levels of soil compaction were evaluated. A summary of test results for the four rounds of post testing are shown in Tables 2 through 7.

5.2 ROUND 1 TESTING

Eleven tests were performed on 6-in. x 8-in. (152-mm x 203-mm) wood posts embedded 40 in. (1,016 mm) in different soils and impacted at various speeds. Two major conclusions came from this round of testing. First, the resistance to post rotation provided by the 2-in. to 4-in. (51-mm to 102-mm) wall-facing rock was dramatically less than that observed in standard strong soil, e.g., AASHTO Grading B. Thus, a standard MGS should not be configured with posts placed in larger wall-facing rock. Second, testing at various impact speeds demonstrated an increase in force and energy absorbed with increases in impact velocity. A 50 percent increase in average force occurred when comparing the 20 mph (32 km/h) tests to the 15 mph (24 km/h) tests, but a minimal increase occurred between the 20 mph (32 km/h) and 25 mph (40 km/h) tests. Further testing would be required to determine whether this phenomenon was the result of the soil inertia, the dynamic properties of the soil, or some other unknown cause.

5.3 ROUND 2 TESTING

Four dynamic posts tests were performed - two tests on 6-in. x 8-in. (152-mm x 203-mm) wood posts and two tests on W6x16 (W152x23.8) steel posts. A W6x16 (W152x23.8) steel section was used in lieu of a W6x9 (W152x13.4) steel section to determine the post-soil resistance of an embedded guardrail post. The heavier post section had a similar flange width but provided reduced concerns for plastic deformations. All four posts were embedded 40 in. (1,016 mm) into a well-compacted, strong soil and impacted at 20 mph (32 km/h). The test results showed that the post-soil resistance for standard wood and steel posts was nearly identical. This finding supports the common, industry-wide assumption that the two post types provide equivalent post-soil resistance for guardrail systems. As such, it is the researcher's opinion that the standard MGS installed in level terrain would perform in an acceptable manner when supported by 6-in. x 8-in. (152-mm x 203-mm) wood posts using a 6-ft (1.8-m) length and a 40-in. (1,016-mm) embedment depth.

5.4 ROUND 3 TESTING

Five tests were performed on wood and steel posts placed at the slope break point of a 3H:1V fill slope with various embedment depths, ranging between 40 in. and 52 in. (1,016 mm and 1,321 mm). A 6-in. x 8-in. (152-mm x 203-mm) wood post with a 52-in. (1,321-mm) post embedment depth was shown to fracture and thus could not provide the required energy absorption for an MGS post. The steel post tests resulted in similar resistances to post rotation regardless of the embedment depth due to plastic bending of the posts during all of the tests. Due to a failure observed in the first test within Round 3, the wood post test matrix was temporarily aborted. As a result, the dynamic post-soil behavior and an acceptable length for a 6-in x 8-in. (152-mm x 203 mm) wood post was not determined for MSE wall applications. Further bogie testing of wood posts installed at the slope break point of a 3H:1V fill slope is planned for a follow-on research and testing program to determine an acceptable post length. If that wood post testing program is successful, the implementation of wood posts into the barrier system may be hindered unless an acceptable post installation method is developed for MSE wall applications.

The cross-sectional area is much larger for wood posts than for steel guardrail posts. Thus, it may be difficult to either drive wood posts or install them using the auger, backfill, and tamping method due to the roller-compacted, strong soil and steel wire mesh found within the upper surface of a wire-faced, MSE wall. Based on post-soil performance, reliability, and ease of installation, steel posts versus wood posts were recommended for continued evaluation for a non-blocked, MGS installed on a wire-faced, MSE wall system.

5.5 ROUND 4 TESTING

Six dynamic component tests were performed to evaluate standard steel posts, ranging from 6 to 7 ft (1.8 and 2.1 m) in length, installed adjacent to and on top of a wire-faced MSE wall system. The posts were driven into a roller-compacted, strong soil at the slope break point of a 3H:1V fill slope. Multiple embedment depths, ranging from 40 in. to 52 in. (1,016 mm to 1,321 mm), were again evaluated. From the test results, these steel posts of different lengths provide similar postsoil behavior (i.e., force versus deflection curves) through the deflections of 15 to 20 in. (381 to 408 mm) or within the expected performance for typical W-beam guardrail systems. However, the 6-ft (1.8-m) long posts with a 40-in. (1,016-mm) embedment depth provided improved energy absorption as compared to the steel posts with embedment depths of 46 and 52 in. (1,168 and 1.321 mm). The greater embedment depths resulted in higher peak post-soil resistance, increased greater post bending, but reduced post rotation. The larger embedment depths caused the point of rotation (plastic bending hinge) to be farther below the groundline, thus resulting in a lower maximum deflection and decreased energy absorption. On the other hand, the lower embedment depths allowed for more post rotation through the soil and less post bending, thus resulting in larger deflections and increased energy absorption. The results from the Round 4 testing program are also shown in Figures 12 and 13.

5.6 POST DESIGN CONSIDERATIONS AND SYSTEM RECOMMENDATIONS

From the Rounds 3 and 4 component testing programs, post-soil forces and energy dissipation characteristics for steel posts were compared to those results obtained from the original MGS research and development program. [See references 4-6, 24.] From that original study, the baseline average post-soil resistance for standard steel posts installed in level terrain was found to be approximately 6.4 kips (28.5 kN) over 15 in. (381 mm) of deflection. From the FHWA testing program described herein, a standard 6-ft (1.8-m) long steel guardrail post installed at the slope break point of the sloped MSE wall system provided an average post-soil resistance of 9.8 kips (43.6 kN) over 15 in. (381 mm) of deflection. Thus, the research team believed that the 6-ft (1.8-m) long steel post would allow the MGS to perform in an acceptable manner and meet current impact safety standards but with reduced barrier deflections from those observed in the original R&D program.

Following the completion of the post testing program, a non-blocked version of the MGS was recommended for evaluation within a crash testing program using: (1) steel W-beam backup plates; (2) 6-ft (1.8-m) long posts manufactured from either W6x8.5 (W152x12.6) or W6x9 (W152x13.4) steel sections; (3) posts driven at the slope break point of a 3H:1V fill slope adjacent to and on top of a wire-faced, MSE wall; and (4) posts installed using a 40-in. (1,016-mm) embedment depth.

CHAPTER 6. SYSTEM DESIGN DETAILS

The standard MGS formed the basis for the barrier system utilized with the wire-faced, mechanically-stabilized earth (MSE) wall system. However, the MGS was modified by removing the 12-in. (305-mm) deep wood spacer blocks and incorporating W-beam backup plates. In addition, all other MGS features were maintained, including the use of 6-ft (1.8-m) long W6x8.5 (W152x12.6) steel posts, rail splices at mid-span locations, a 31-in. (787-mm) top mounting height, as well as the 75-in. (1,905-mm) post spacing. The non-blocked MGS was installed at the slope break point of a 3H:1V fill slope using an approximate lateral offset of 6 ft (1.8 m) from the post centerline to the outer edge of the wire-faced, MSE wall.

The test installation was 175 ft (53.3 m) long and consisted of standard 12-gauge (2.66-mm thick) corrugated W-beam guardrail supported by steel posts, as shown in Figures 14 through 30. Photographs of the test installation are shown in Figures 31 through 45. Material specifications, mill certifications, and certificates of conformity for the system materials are shown in Appendix A.

The entire system was constructed with twenty-nine guardrail posts. Post nos. 3 through 27 were galvanized ASTM A36 W6x8.5 (W152x12.6) steel sections measuring 72 in. (1,829 mm) long. Post no. 1, 2, 28, and 29 utilized timber Breakaway Cable Terminal (BCT) posts measuring $5\frac{1}{2}$ in. wide x $7\frac{1}{2}$ in. deep x 46 in. long (140 mm x 190 mm x 1,168 mm) and were placed in 72-in. (1,829-mm) long steel foundation tubes, as shown in Figures 14, 26, and 28. A tangent anchorage system was utilized on the upstream and downstream ends of the guardrail system in order to develop the barrier's tensile capacity. The anchorage system consisted of timber posts, foundation tubes, anchor cables, bearing plates, rail brackets, and channel struts, which closely resembled the hardware used in the Modified BCT system.

Post nos. 1 through 29 were spaced on 75 in. (1,905 mm) centers. For posts nos. 3 through 27, the soil embedment depth was 40 in. (1,016 mm), as shown in Figure 24. Post nos. 9 through 21 were driven into the soil at the slope break point of the 6-ft (1,829-mm) wide, 3H:1V fill slope located on the wire-faced, MSE wall. Wood spacer blockouts were not used to offset the rail away from the front face of the steel posts. However, 12-gauge (2.66-mm thick) W-Beam backup plates, measuring 12 in. (305 mm) long, were located between the rail and the front face of the steel posts, as shown in Figure 24.

Standard 12-gauge (2.66-mm thick) W-beam rails with additional post bolt slots at half-post spacing intervals were placed between post nos. 1 and 29, as shown in Figures 14 and 25. The top mounting height of the W-beam guardrail was 31 in. (787 mm) with a 24% in. (632 mm) center height. Rail splices were placed at the mid-span locations between posts, as shown in Figures 14 and 26. All guardrail splice connections between the rail sections were lapped in the direction of traffic to reduce vehicle snag at the splice during the crash tests.

The actual, wire-faced, MSE wall system measured 84 ft (25.6 m) in length and was configured with a 3H:1V fill slope at its outer edge. The MSE wall system was positional longitudinally between post nos. 8 through 22, as shown in Figures 16 and 17. The MSE wall system was placed within an excavated pit measuring 11 ft - 10 in. (3.6 m) wide by 7 ft (2.1 m) deep with

three 2-ft (0.6-m) thick layers of roller-compacted, course, crushed limestone material. The soil-aggregate material met the Grading B specifications of AASHTO M147-65 denoted in MASH and NCHRP Report No. 350, which also closely conformed to the select wall backfill materials denoted in Sections 255 and 704 of the 2003 FHWA *Standard Specifications for Construction of Roads and Bridges on Federal Highway Projects*. [14,25,26] The outer region of the bottom two layers contained a wall facing fill material that consisted of 4 to 6-in. (102 to 152-mm) diameter rocks that were placed by hand. A 4-ft (1.2-m) wide void space was excavated behind the MSE wall system. Steel-wire reinforcement mats were used to construct and stabilize the MSE wall system, as shown in Figures 17 through 23. The MSE wall installation manual is shown in Appendix B.

For test no. MGSGW-1 (1100C small car test), the W-beam backup plates at post nos. 14 through 17 were longitudinally shifted to different positions in order to determine whether rail slot alignment, or mis-alignment, affects post bolt release away from the rail. The bolt heads were also positioned at different locations within the guardrail slots. For post nos. 14 and 16, the guardrail slots and W-beam backup plate slots were mis-aligned. For post nos. 15 and 17, the guardrail slots and W-beam backup plate slots were aligned with one another. The four post bolts and rail slots are depicted in Figure 42.

For test no. MGSGW-2 (2270P pickup truck test), the head of the post bolts were positioned at different locations within the guardrail slots. For post nos. 12 through 17, three different locations were considered - the upstream end of the slot, the downstream end of the slot, and centered in slot. These configurations are shown in Figures 43 through 45.

CHAPTER 7. TEST REQUIREMENTS AND EVALUATION CRITERIA

7.1 TEST REQUIREMENTS

Longitudinal barriers, such as W-beam guardrails, must satisfy impact safety standards in order to be accepted by the Federal Highway Administration (FHWA) for use on the National Highway System (NHS) for new construction projects or as a replacement for existing designs not meeting current safety standards. In recent years, these safety standards have consisted of the guidelines and procedures published in NCHRP Report No. 350.^[25] However, NCHRP Project 22-14(2) generated revised testing procedures and guidelines for use in the evaluation of roadside safety appurtenances and are provided in MASH.^[14] According to Test Level 3 (TL-3) of MASH, longitudinal barrier systems must be subjected to two full-scale vehicle crash tests. The two full-scale crash tests are noted below.

- 1. Test Designation No. 3-10 consists of a 2,425-lb (1,100-kg) passenger car impacting the system at a nominal speed and angle of 62 mph (100 km/h) and 25 degrees, respectively.
- 2. Test Designation No. 3-11 consists of a 5,000-lb (2,268-kg) pickup truck impacting the system at a nominal speed and angle of 62 mph (100 km/h) and 25 degrees, respectively.

The test conditions of TL-3 longitudinal barriers are summarized in Table 8.

	Test Designation No.	Test Vehicle	Imp	act Condit	Evaluation Criteria ¹	
Test Article			Speed			Angle
			mph	km/h	(deg)	J = 32.1 W
Longitudinal	3-10	1100C	62	100	25	A,D,F,H,I
Barrier	3-11	2270P	62	100	25	A,D,F,H,I

Table 8. MASH TL-3 Crash Test Conditions.

7.2 EVALUATION CRITERIA

Evaluation criteria for full-scale vehicle crash testing are based on three appraisal areas: (1) structural adequacy; (2) occupant risk; and (3) vehicle trajectory after collision. Criteria for structural adequacy are intended to evaluate the ability of the guardrail to contain and redirect impacting vehicles. In addition, controlled lateral deflection of the test article is acceptable. Occupant risk evaluates the degree of hazard to occupants in the impacting vehicle. Vehicle trajectory after collision is a measure of the potential for the post-impact trajectory of the vehicle to result in multi-vehicle accidents. This criterion also indicates the potential for safety hazard for the occupants of other vehicles or occupants of the crash vehicle when subjected to secondary

⁻ Evaluation criteria explained in Table 9.

collisions with other fixed objects. These three evaluation criteria are described in greater detail in MASH and are summarized in Table 9. Finally, the full-scale vehicle crash tests were conducted and reported in accordance with the procedures provided in MASH.

In addition to the standard occupant risk measures, the Post-Impact Head Deceleration (PHD), the Theoretical Head Impact Velocity (THIV), and the Acceleration Severity Index (ASI) were determined and reported on the test summary sheets. Additional discussion on PHD, THIV, and ASI is provided in Reference 14.

Table 9. MASH Evaluation Criteria for Longitudinal Barriers.

	Table 7. MASH Evaluation				
Structural Adequacy		should not penetra	ticle or bring the vehicle to a te, underride, or override the ction of the test article is		
	D. Detached elements, fragments or other debris from the test article should not penetrate or show potential for penetrating the occupant compartment, or present an undue hazard to other traffic, pedestrians, or personnel in a work zone. Deformations of, or intrusions into, the occupant compartment should not exceed limits set forth in Section 5.3 and Appendix E of MASH.				
	after collision. The maximum				
	H. Occupant Impact Velocity (OIV) (see Appendix A, Section A5.3 of MASH for calculation procedure) should satisfy the following limits:				
Occupant	Occupant Impact Velocity Limits				
Risk	Component	Preferred	Maximum		
	Longitudinal and Lateral	30 ft/s (9.1 m/s)	40 ft/s (12.2 m/s)		
I. The Occupant Ridedown Acceleration (ORA) (see Appendix A, of MASH for calculation procedure) should satisfy the following l					
	Occupant Ridedown Acceleration Limits				
	Component	Preferred	Maximum		
	Longitudinal and Lateral	15.0 g's	20.49 g's		

7.3 SOIL STRENGTH REQUIREMENTS

In order to limit the variation of soil strength among testing agencies, the foundation soil must satisfy the recommended performance characteristics set forth in Chapter 3 and Appendix B of MASH. Testing facilities must first subject the baseline soil material to a dynamic post test to

demonstrate a minimum dynamic load of 7.5 kips (33.4 kN) at deflections between 5 and 20 in. (127 and 508 mm). If satisfactory results are observed, a static test is conducted using an identical test installation. The results from this static test become the baseline requirement for soil strength in future full-scale crash testing. On the day of the full-scale crash test, an additional steel post is to be statically tested in the same manner as used for the baseline static test. If the static test results reveal a post-soil resistance equal to or greater than 90 percent of the baseline test result at deflections of 5, 10, and 15 in. (127, 254, and 381 mm), the full-scale crash test can be conducted. Otherwise, the crash test must be postponed until the soil demonstrates adequate post-soil strength. However, the soil strength tests were not conducted for this crash testing program since a special soil material was required and placed with a roller-compactor in a region where the guardrail posts were driven.

CHAPTER 8. TEST CONDITIONS

8.1 TEST FACILITY

The testing facility is located at the Lincoln Air Park on the northwest side of the Lincoln Municipal Airport and is approximately 5 miles (8.0 km) northwest of the University of Nebraska-Lincoln.

8.2 VEHICLE TOW AND GUIDANCE SYSTEM

A reverse cable tow system with a 1:2 mechanical advantage was used to propel the test vehicle. The distance traveled and the speed of the tow vehicle were one-half that of the test vehicle. The test vehicle was released from the tow cable before impact with the barrier system. A digital speedometer on the tow vehicle increased the accuracy of the test vehicle impact speed.

A vehicle guidance system developed by Hinch was used to steer the test vehicle.^[27] A guideflag, attached to the left-front wheel and the guide cable, was sheared off before impact with the barrier system. The ¾-in. (9.5-mm) diameter guide cable was tensioned to approximately 3,500 lb (15.6 kN) and supported both laterally and vertically every 100 ft (30.48 m) by hinged stanchions. The hinged stanchions stood upright while holding up the guide cable, but as the vehicle was towed down the line, the guide-flag struck and knocked each stanchion to the ground.

8.3 TEST VEHICLES

For test no. MGSGW-1, a 2003 Kia Rio Sedan was used as the test vehicle. The curb, test inertial, and gross static vehicle weights were 2,302 lb (1,044 kg), 2,427 lb (1,101 kg), and 2,596 lb (1,178 kg), respectively. The test vehicle is shown in Figure 46, and vehicle dimensions are shown in Figure 47.

For test no. MGSGW-2, a 2003 Dodge Ram Quad Cab pickup truck was used as the test vehicle. The curb, test inertial, and gross static vehicle weights were 5,081 lb (2,305 kg), 4,999 lb (2,268 kg), and 5,169 lb (2,345 kg), respectively. The test vehicle is shown in Figure 48, and vehicle dimensions are shown in Figure 49.

The longitudinal component of the center of gravity (c.g.) was determined using the measured axle weights for both the small car and pickup truck. The Suspension Method was used to determine the vertical component of the c.g. for the pickup truck. This method is based on the principle that the c.g. of any freely suspended body is in the vertical plane through the point of suspension. The vehicle was suspended successively in three positions, and the respective planes containing the c.g. were established. The intersection of these planes pinpointed the c.g. location for the test inertial condition. The c.g. height of the 1100C vehicle was estimated based on historical c.g. height measurements. The location of the final c.g. for each vehicle is shown in Figures 47 and 49 through 51. Data used to calculate the final location of the c.g. is shown in Appendix C.

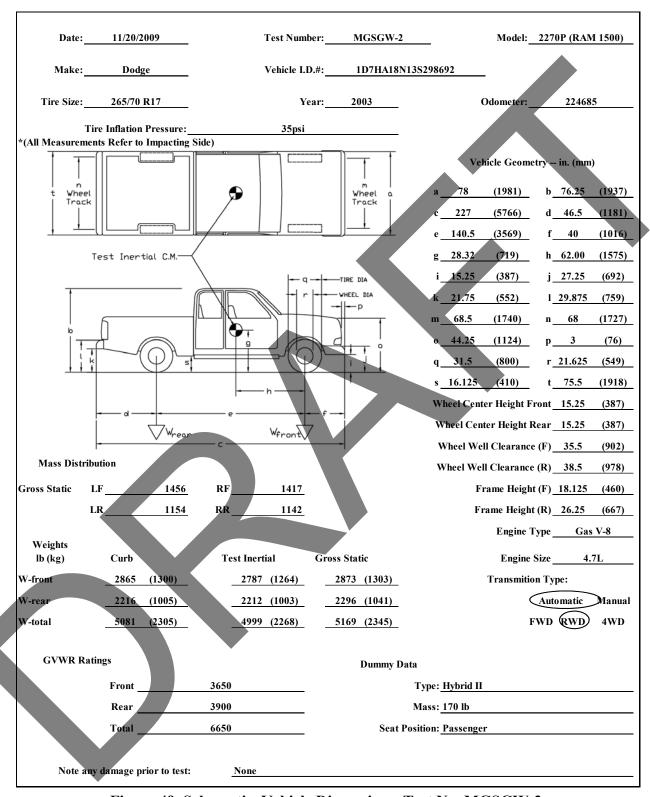

Figure 49. Schematic. Vehicle Dimensions, Test No. MGSGW-2.

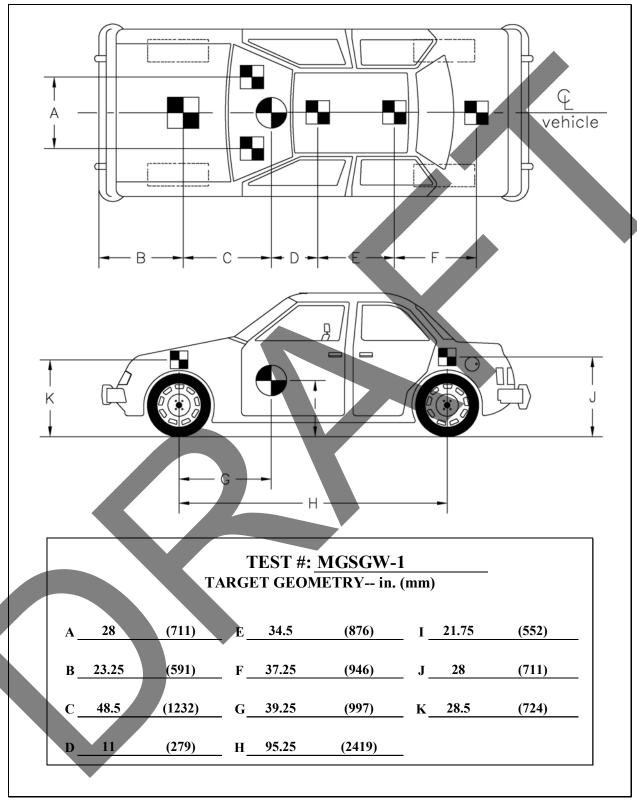

Figure 50. Schematic. Target Geometry, Test No. MGSGW-1.

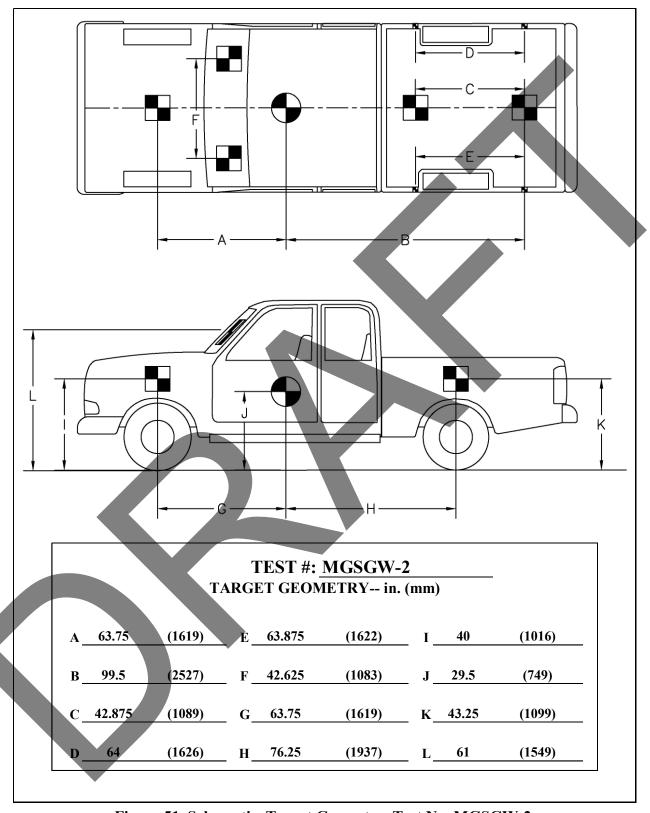

Figure 51. Schematic. Target Geometry, Test No. MGSGW-2.

Square black- and white-checkered targets were placed on the vehicles to aid in the analysis of the high-speed digital videos, as shown in Figures 50 and 51. Round, checkered targets were placed on the center of gravity on the left-side door, the right-side door, and the roof of the vehicles. The remaining targets were located for references so they could be viewed from the high-speed cameras for video analysis.

The front wheels of the test vehicles were aligned for camber, caster, and toe-in values of zero so that the vehicles would track properly along the guide cable. A 5B flash bulb was mounted under the left-side windshield wiper and was fired by a pressure tape switch mounted at the impact corner of the bumper. The flash bulb was fired upon initial impact with the test article to create a visual indicator of the precise time of impact on the high-speed digital videos. A remote controlled brake system was installed in the test vehicles so the vehicles could be brought safely to a stop after the test.

8.4 SIMULATED OCCUPANT

For test nos. MGSGW-1 and MGSGW-2, A Hybrid II 50th Percentile Adult Male Dummy, equipped with clothing and footware, was placed in the right-front seat of the test vehicle with the seat belt fastened. The dummy, which had a final weight of 170 lb (77 kg), was represented by model no. 572, serial no. 451, and was manufactured by Android Systems of Carson, California. As recommended by MASH, the dummy was not included in calculating the c.g location.

8.5 DATA ACQUISITION SYSTEMS

8.5.1 Accelerometers

Two environmental shock and vibration sensor/recorder systems were used to measure the accelerations in the longitudinal, lateral, and vertical directions. All of the accelerometers were mounted near the center of gravity of the test vehicles.

The first accelerometer system was a two-arm piezoresistive accelerometer system manufactured by Endeveo of San Juan Capistrano, California. Three accelerometers were used to measure each of the longitudinal, lateral, and vertical accelerations independently at a sample rate of 10,000 Hz. Two additional accelerometers were used to measure the longitudinal and lateral accelerations independently at the same sample rate. The accelerometers were configured and controlled using a system developed and manufactured by Diversified Technical Systems, Inc. (DTS) of Seal Beach, California. More specifically, data was collected using a DTS Sensor Input Module (SIM), Model TDAS3-SIM-16M. The SIM was configured with 16 MB SRAM memory and 8 sensor input channels with 250 kB SRAM/channel. The SIM was mounted on a TDAS3-R4 module rack. The module rack was configured with isolated power/event/communications, 10BaseT Ethernet and RS232 communication, and an internal backup battery. Both the SIM and module rack were crashworthy. The "DTS TDAS Control" computer software program and a customized Microsoft Excel worksheet were used to analyze and plot the accelerometer data.

The second system, Model EDR-3, was a triaxial piezoresistive accelerometer system developed by Instrumented Sensor Technology (IST) of Okemos, Michigan. The EDR-3 was configured with 256 kB of RAM memory, a range of ±200 g's, a sample rate of 3,200 Hz, and a 1,120 Hz lowpass filter. The computer software program "DynaMax 1 (DM-1)" and a customized Microsoft Excel worksheet were used to analyze and plot the accelerometer data.

8.5.2 Rate Transducers

An angle rate sensor, the ARS-1500, with a range of 1,500 degrees/sec in each of the three directions (roll, pitch, and yaw) was used to measure the rates of rotation of the test vehicles. The angular rate sensor was mounted on an aluminum block inside the test vehicles near the center of gravity and recorded data at 10,000 Hz to the SIM. The raw data measurements were then downloaded, converted to the proper Euler angles for analysis, and plotted. The computer software program "DTS TDAS Control" and a customized Microsoft Excel worksheet were used to analyze and plot the angular rate sensor data.

8.5.3 Pressure Tape Switches

For test nos. MGSGW-1 and MGSGW-2, five pressure-activated tape switches, spaced at approximately 6.56-ft (2-m) intervals, were used to determine the speed of the vehicles before impact. Each tape switch fired a strobe light which sent an electronic timing signal to the data acquisition system as the right-front tire of the test vehicle passed over it. Test vehicle speeds were determined from electronic timing mark data recorded using TestPoint and LabVIEW computer software programs. Strobe lights and high-speed video analysis are used only as a backup in the event that vehicle speed cannot be determined from the electronic data. However, due to technical difficulties, the strobe data was not collected with the LabVIEW computer software program for test no. MGSGW-1.

8.5.4 High-Speed Photography

Two high-speed AOS VITcam digital video cameras, three high-speed AOS X-PRI digital video cameras, four JVC digital video cameras, and two Canon digital video cameras were utilized to film both tests. Camera details, camera operating speeds, lens information, and a schematic of the camera locations relative to the system for both tests are shown in Figures 52 and 53. The high-speed digital videos were analyzed using the ImageExpress MotionPlus and Redlake MotionScope software. Actual camera speed and camera divergence factors were considered in the analysis of the high-speed digital videos. A Nikon D50 digital still camera was also used to document pre-test and post-test conditions for both tests.

CHAPTER 9. FULL-SCALE CRASH TEST NO. MGSGW-1

9.1 TEST NO. MGSGW-1

The 2,596-lb (1,178-kg) small car with a simulated occupant seated in the right-front seat, impacted the non-blocked MGS placed at the slope break point of the 3H:1V fill slope on top of a wire-faced, MSE wall at a speed of 61.0 mph (98.2 km/h) and at an angle of 25.3 degrees. A summary of the test results and sequential photographs are shown in Figure 54. Additional sequential photographs are shown in Figures 55 and 56. Documentary photographs of the crash test are shown in Figures 57 and 58.

9.2 WEATHER CONDITIONS

Test no. MGSGW-1 was conducted on October 20, 2009 at approximately 1:30 pm. The weather conditions as per the National Oceanic and Atmospheric Administration (station 14939/LNK) were documented and are shown in Table 10.

9.3 TEST DESCRIPTION

Initial vehicle impact was to occur 4 ft - $9\frac{1}{2}$ in. (1.5 m) upstream of the splice between post nos. 14 and 15, as shown in Figure 59. The actual point of impact was $4\frac{1}{2}$ in. (114 mm) downstream from the target impact location, or 4 ft - 5 in. (1.3 m) upstream from the centerline of the splice between post nos. 14 and 15. A sequential description of the impact events is shown in Table 11. The vehicle came to rest 31 ft - 1 in. (9.5 m) downstream from impact and 11 ft - 3 in. (3.4 m) laterally in front of the traffic-side face of the barrier and oriented with its front end facing upstream. The vehicle trajectory and final position are shown in Figures 54 and 60.

Table 11. Sequential Description of Impact Events, Test No. MGSGW-1.

TIME	. Sequential Description of Impact Events, Test No. MGSGW-1.
(sec)	EVENT
0.000	The vehicle impacted the system.
0.018	The right-front bumper of the vehicle underrode the rail.
0.022	The right-front tire contacted the front-upstream flange of post no. 14.
0.03	The rail disengaged from post no. 14.
0.044	The engine block contacted the rail at splice between post nos. 14 and 15.
0.058	The vehicle rolled away from the barrier.
0.068	The center of the front bumper contacted the upstream side of post No. 15.
0.070	The right-front tire deflated.
0.074	The rail disengaged from post no. 15, which twisted downstream.
0.078	The right-front tire became airborne.
0.112	The surrogate occupant's head contacted the right-front side window, causing the window to shatter.
0.116	The right-rear tire became airborne.
0.128	The front bumper overrode post no. 15.
0.158	The center-front bumper contacted the front-upstream flange of post no. 16.
0.174	The rail separated from post no. 16.
0.188	The left-front tire deflated.
0.272	A buckle formed in bottom rail corrugation just downstream of post no. 16.
0.276	The front bumper contacted post no. 17, which twisted upstream.
0.282	The vehicle pitched downward.
0.306	The rail disengaged from post no. 17.
0.322	The right-front tire contacted the ground.
0.328	The vehicle yawed toward the barrier.
0.726	The right-front corner of the engine hood lost contact with the rail at post no. 18, and the vehicle exited the system at an angle of 58.3 degrees with a velocity of 10.2 mph (16.3 km/h).
0.826	Left front of vehicle yaws toward barrier.
1,346	Front of vehicle continues to yaw toward barrier.

9.4 BARRIER DAMAGE

Damage to the barrier was moderate, as shown in Figures 61 through 66. Barrier damage consisted of contact marks on and deformation to the guardrail posts and W-beam fail. The length of vehicle contact along the barrier was approximately 24 ft - 2 in. (7.4 m) extending from 53 in. (1,346 mm) upstream of the centerline of the splice between post nos. 14 and 15 to 26 in. (660 mm) upstream of post no. 18 m

Damage to the W-beam rail occurred between posts nos. 13 and 18. Minor buckling was found just upstream of post no. 13. Sheet metal from the vehicle body was wedged in the guardrail slot near post no. 14. A ½-in. (6-mm) gap was found at the splice between post nos. 14 and 15. General deformation and flattening in the rail splice between posts nos. 16 and 17. Between posts nos. 16 and 17, the splice bolt holes encountered a ½-in. (3-mm) gap. At post no. 17, the bottom of the backup plate was crushed upward with a 1-in. (25-mm) tear on the upstream side. The guardrail bolt and backup plate were still attached to post no. 17, while the slot in the guardrail was folded with a ½-in. (13-mm) tear. Minor buckling occurred at post nos. 17 and 18.

A 2½-in. (64-mm) soil gap was found at the front of post no. 13. Post nos. 14 and 15 twisted and bent downstream. The front flange of post no. 14 was bent and sustained contact marks. A 4-in. (102-mm) soil gap was found at the front of post no 14. The guardrail bolt tore through the flange of post no. 14. The guardrail bolt tore through the flange at post nos. 14 through 16. Posts nos. 16 and 17 were completely removed from the ground, with the wire mesh being exposed at the bottom of the hole at post no. 16. The front flange of post no. 16 was deformed due to contact with the vehicle. Post no. 17 was bent at the groundline and at the location of vehicle contact, and it was severely twisted. Post no. 18 twisted upstream, and its front flange buckled due to vehicle contact. An ½-in. (3-mm) gap was found at the front of post no. 18.

The permanent set of the barrier system is shown in Figure 61. The maximum lateral permanent set rail and post deflections were $17\frac{3}{8}$ in. (441 mm) at the midspan between post nos. 15 and 16 and $20\frac{1}{8}$ in. (511 mm) at post no. 14, respectively, as measured in the field. The maximum lateral dynamic rail and post deflections were 27.4 in (696 mm) at the midspan between post nos. 15 and 16 and 26.2 in. (665 mm) at post no. 14, respectively, as determined from high-speed digital video analysis. The working width of the system was found to be 35.7 in. (907 mm).

9.5 VEHICLE DAMAGE

The damage to the vehicle was moderate, as shown in Figures 67 through 70. The maximum occupant compartment deformations are shown in Table 12 with the deformation limits established in MASH for various regions of the occupant compartment. It should be noted that the MASH-established deformation limits were not violated. Complete interior occupant compartment deformations as well as other vehicle deformations, along with the corresponding locations, are provided in Appendix D.

The majority of the damage was concentrated on the right-front corner and right side of the vehicle where the impact occurred. The front bumper was completely detached and fractured. The front frame was deformed inward toward the engine compartment and fractured on the right

side. The metal headlight assembly frame was deformed inward, and the headlight was disengaged from the vehicle. The right-front A-arm assembly was disengaged from the frame. The right-front fender was torn back to approximately the midpoint of the wheel and became detached. The engine support bowed downward and backward. Both front tires were deflated. Two gouge marks were found along the right side, measuring 27½ in. (692 mm) and 19 in. (483 mm) in length. The hood and radiator were crushed inward at the right bumper corner. The right-front window was fractured, and the glass removed. A 7-in. (178-mm) scratch was found on the underside of the fender. Severe folding occurred on the right-front quarter panel. Minor denting was found along the bottom of the right-front door. The right-front wheel was deformed. The right-front side of the interior floor panel was deformed inward and upward. Both right-side doors were partially detached at the hinge.

Table 12. Maximum Occupant Compartment Deformation by Location, Test No. MGSGW-1.

LOCATION	MAXIMUM DEFORMATION in. (mm)	MASH ALLOWABLE DEFORMATION in. (mm)

Side Door (Above Seat)	³/ ₄ (19)	≤ 9 (229)
Side Door (Below Seat)	11/4 (32)	≤ 12 (305)
Roof	NA	≤ 4 (102)
Windshield	NA	≤ 3 (76)

9.6 OCCUPANT RISK

The calculated occupant impact velocities (OIVs) and maximum 0.010-sec occupant ridedown accelerations (ORAs) in both the longitudinal and lateral directions are shown in Table 13. It is noted that the OIVs and ORAs were within the suggested limits provided in MASH. The calculated THIV, PHD, and ASI values are also shown in Table 13. The results of the occupant risk analysis, as determined from the accelerometer data, are summarized in Figure 54. The recorded data from the accelerometers and the rate transducers are shown graphically in Appendix E.

Table 13. Summary of OIV, ORA, THIV, PHD, and ASI Values, Test No. MGSGW-1.

Evaluation Criteria		Transducer			MASH
		EDR-3	DTS set 1	DTS set 2	Limits
OIV	Longitudinal	-22.62 (-6.89)	-25.87 (-7.89)	-22.45 (-6.84)	≤ 40 (12.2)
ft/s (m/s)	Lateral	-16.51 (-5.03)	-17.07 (-5.20)	-16.53 (-5.04)	≤40 (12.2)
ORA	Longitudinal	-9.94	-13.78	-10.25	≤ 20.49
g's	Lateral	-6.54	-7.81	-7.40	≤ 20.49
f	THIV t/s (m/s)	NA	30.08 (9.17)	NA	not required
	PHD g's	NA	14.55	NA	not required
	ASI	0.74	0.92	0.78	not required

9.7 DISCUSSION

The analysis of the test results for test no. MGSGW-1 showed that the non-blocked MGS placed at the slope break point of the 3H:1V fill slope on top of a wire-faced, MSE wall adequately contained and redirected the 1100C vehicle with controlled lateral displacements of the barrier. There were no detached elements nor fragments which showed potential for penetrating the occupant compartment nor presented undue hazard to other traffic. Deformations of, or intrusions into, the occupant compartment that could have caused serious injury did not occur. The test vehicle did not penetrate nor ride over the barrier and remained upright during and after the collision. Vehicle roll, pitch, and yaw angular displacements were deemed acceptable because they did not adversely influence occupant risk safety criteria nor cause rollover. After impact, the vehicle exited the barrier at an angle of 58.3 degrees as it spun-out. The vehicle's trajectory violated the bounds of the exit box. However, the exit box criterion is preferable and not a requirement. Therefore, test no. MGSGW-1 (test designation no. 3-10) was determined to be acceptable according to the TL-3 MASH safety performance criteria.

CHAPTER 10. FULL-SCALE CRASH TEST NO. MGSGW-2

10.1 TEST NO. MGSGW-2

The 5,169-lb (2,345-kg) pickup truck with a simulated occupant seated in the right fron seat, impacted the non-blocked MGS placed at the slope break point of the 3H:1V fill slope on top of a wire-faced, MSE wall at a speed of 65.3 mph (105.0 km/h) and at an angle of 25.1 degrees. A summary of the test results and sequential photographs are shown in Figure 71. Additional sequential photographs are shown in Figures 72 and 73. Documentary photographs of the crash test are shown in Figures 74 through 76.

10.2 WEATHER CONDITIONS

Test no. MGSGW-2 was conducted on November 20, 2009 at approximately 2:20 pm. The weather conditions as per the National Oceanic and Atmospheric Administration (station 14939/LNK) were reported and are shown in Table 14.

10.3 TEST DESCRIPTION

Initial vehicle impact was to occur 16 ft (4.9 m) upstream of the splice between post nos. 14 and 15, as shown in Figure 77. The actual point of impact occurred at the target impact point. A sequential description of the impact events is shown in Table 15. The vehicle came to rest 103 ft - $4\frac{1}{2}$ in. (31.5 m) downstream from impact and 16 ft - 3 in. (4.9 m) laterally in front of the barrier. The vehicle trajectory and final position are shown in Figures 71 and 78.

Table 15. Sequential Description of Impact Events, Test No. MGSGW-2.

	Sequential Description of Impact Events, Test No. MGSGW-2.
TIME (sec)	EVENT
0.000	The right-front corner of the vehicle impacted the guardrail.
0.070	The rail separated from post no. 13. The vehicle rolled toward the barrier.
0.078	The right-front tire contacted post no. 13.
0.084	The vehicle began to redirect.
0.104	The right-rear tire contacted the guardrail at the target impact location.
0.108	The right-front door of the vehicle became ajar. The bolt on post no. 14 pulled through rail.
0.148	The right-front tire ruptured.
0.152	The front-right tire contacted post no. 14.
0.184	The left-rear tire became airborne.
0.190	The left-front tire became airborne.
0.230	The vehicle became parallel to the system with a velocity of 46.7 mph (75.2 km/h). The vehicle continued to yaw in the negative direction.
0.248	The right-front tire struck post no. 15.
0.252	The rail separated from post no. 15. The right-front wheel was disengaged from the vehicle.
0.398	The vehicle yawed back in the positive direction.
0.404	The right-rear tire contacted post no. 15 and became airborne.
0.452	The right side of the rear bumper lost contact with the rail at the midpoint between post nos. 14 and 15, and the vehicle exited the system at an angle of 20.4 degrees and a velocity of 43.8 mph (70.5 km/h).
0.700	The driveshaft made contact with the ground, and the vehicle continued to yaw in the negative direction.
0.748	The driveshaft folded and detached from the vehicle.
0.756	The left-front tire contacted the ground.
0.988	The left-front tire became airborne again.
1.168	The left-front tire contacted the ground again.
1.190	The left-rear tire contacted the ground.

10.4 BARRIER DAMAGE

Damage to the barrier was moderate, as shown in Figures 79 through 84. Barrier damage consisted of deformed guardrail posts, contact marks on the W-beam rail and guardrail posts, and deformed W-beam rail. The length of vehicle contact along the barrier was approximately 25 ft – 9½ in. (7.9 m), extending from 5 in. (127 mm) upstream of post no. 12 to 4½ in. (114 mm) downstream of post no. 16.

Contact marks were found on the W-beam rail between the impact location at 16 ft upstream of the splice between post nos. 14 and 15 through $4\frac{1}{2}$ in. downstream of post no. 16. A buckle formed in the rail at 3 in. (76 mm) upstream of post no. 11. Flattening of the lower corrugation occurred from 4 in. (102 mm) downstream of post no. 12 through 20 in. (508 mm) upstream of post no. 14. The bottom of the rail folded from post no. 14 through 19 in. (483 mm) downstream of post no. 15. The rail disengaged from post nos. 13 through 16. Two tears were found in the bottom of the guardrail slots at post nos. 13 through 15, measuring $1\frac{1}{2}$ in. (38 mm), $2\frac{3}{4}$ in. (70 mm), and $1\frac{1}{4}$ in. (32 mm), respectively. The splices between post nos. 12 and 13 and 14 and 15 were stretched $\frac{1}{4}$ in. (6.4 mm) and $\frac{1}{16}$ in. (1.6 mm), respectively.

Post nos. 3 through 10 twisted slightly downstream. Post no. 11 twisted downstream and rotated backward forming a 1-in. (25-mm) soil gap at the front face of the post. Post no. 12 rotated backward, and soil gaps of 4½ in. (114 mm) and 2 in. (51 mm) were found at the front and back faces of the post, respectively. Post no. 13 twisted and bent downstream. The upstream edge of the front flange of post no. 13 encountered local deformation and contact marks, and a sharp kink was found on the back flange. Post no. 14 was bent downstream, and its front flange encountered deformations and contact marks. Post no. 15 was bent downstream and had a 5-in. (127-mm) soil gap at its front flange. The tire of the vehicle came to rest on top of post no. 15. Post no. 16 rotated slightly upstream and had a 2¼-in. (57 mm) soil gap at its front face, and its front flange was slightly deformed near the top. The backup plate at post nos. 13 and 14 disengaged from the system. The remaining posts sustained no damage.

The permanent set of the barrier system is shown in Figure 79. The maximum lateral permanent set rail and post deflections were 22½ in. (565 mm) at post no. 14 and 26¼ in. (667 mm) at post no. 13, respectively, as measured in the field. The maximum lateral dynamic rail and post deflections were 35.7 in (907 mm) at the midpoint of post nos. 13 and 14 and 35.7 in. (907 mm) at post no. 14, respectively, as determined from high-speed digital video analysis. The working width of the system was found to be 45.2 in. (1,148 mm).

10.5 VEHICLE DAMAGE

The damage to the vehicle was moderate, as shown in Figures 85 through 88. The maximum occupant compartment deformations as well as the deformation limits established in MASH for various regions of the occupant compartment are shown in Table 16. It should be noted that the MASH-established deformation limits were not violated. Complete interior occupant compartment deformations as well as other vehicle deformations, along with the corresponding locations, are provided in Appendix D.

The majority of the damage was concentrated on the right-front corner and the right side of the vehicle. The right-front wheel was detached, and the brake lines were cut. The right control arm was sheared off, and the upper A-arm was bent downward. Denting occurred to the inner right-front wheel well. The lower-right side of the front bumper was crushed upward, and the bumper sustained contact marks. The right-front quarter panel was crushed slightly inward, and the right headlight was fractured. The hood was slightly ajar, and cracking occurred along the right side of the grill. The right-front door was crushed inward at the lower hinge and slightly ajar. Crushing and scraping occurred along the entire lower length of the vehicle. The right-rear quarter panel and the bumper encountered denting and folding. The driveshaft was removed from the vehicle. The right-rear taillight was displaced, and the right side of the tailgate was slightly ajar. The left-rear wheel was detached. A 3-in. (76-mm) diameter bulge was found in the sidewall of the right-rear tire.

10.6 OCCUPANT RISK

The calculated occupant impact velocities (OIVs) and maximum 0.010-sec occupant ridedown accelerations (ORAs) in both the longitudinal and lateral directions are shown in Table 17. It is noted that the OIVs and ORAs were within the suggested limits provided in MASH. The calculated THIV, PHD, and ASI values are also shown in Table 17. The results of the occupant risk analysis, as determined from the accelerometer data, are summarized in Figure 71. The recorded data from the accelerometers and the rate transducers are shown graphically in Appendix F.

10.7 DISCUSSION

The analysis of the test results for test no. MGSGW-2 showed that the non-blocked MGS placed at the slope break point of the 3H:1V fill slope on top of a wire-faced, MSE wall adequately contained and redirected the 2270P vehicle with controlled lateral displacements of the barrier. There were no detached elements nor fragments which showed potential for penetrating the occupant compartment nor presented undue hazard to other traffic. Deformations of, or intrusions into, the occupant compartment that could have caused serious injury did not occur. The test vehicle did not penetrate nor ride over the barrier and remained upright during and after the collision. Vehicle roll, pitch, and yaw angular displacements were deemed acceptable because they did not adversely influence occupant risk safety criteria nor cause rollover. After impact, the vehicle exited the barrier at an angle of 20.4 degrees. The vehicle's trajectory violated the bounds of the exit box as it spun-out. However, the exit box criterion is preferable and not a requirement. Therefore, test no. MGSGW-2 (test designation no. 3-11) was determined to be acceptable according to the TL-3 MASH safety performance criteria.

CHAPTER 11. SUMMARY, CONCLUSIONS, AND RECOMMENDATIONS

A design review, cost comparison, and evaluation was performed on selected barrier concepts for consideration in protecting hazardous conditions that arise from the construction of wire-faced, MSE wall systems. After eliminating general concepts that utilized deeply-embedded reinforced concrete foundations and long, sloped tension elements, five barrier concepts remained for further investigation and analysis. During the evaluation process, a cost comparison was made between different barrier types as well as on the effect of their use in the construction of wire-faced, MSE walls. From this effort, a non-blocked MGS with steel posts placed at the slope break point of a 3H:1V fill slope (Concept no. 4) was found to provide the greatest net cost reduction, or \$158/ft, when compared to the baseline configuration of standard MGS with steel posts and a 2-ft (610-mm) lateral offset to the slope break point (Concept no. 1). Based on the cost analysis and system comparison, the CFLHD-MwRSF project team selected Concept no. 4 for further development and consideration for protecting vertical drop-offs associated with wire-faced, MSE walls.

During this study, a significant dynamic bogie testing program was conducted to determine the post-soil behavior of steel and wood posts embedded in level and/or sloped terrain using a compacted soil material similar to that used for the construction of wire-faced, MSE walls. This post testing program was also used to evaluate different post placement methods, such as the auger, backfill, and tamp method versus driven posts, as well as to select the appropriate post length, determine the preferred post material, and evaluate the propensity for damage to occur to wire-faced, MSE walls during vehicular impacts into the barrier system. A total of 26 dynamic bogie tests were performed and are described in detail in an MwRSF research report. [23] From this effort, a 6-ft (1.8-m) long steel guardrail post with a 40-in. (1,016-mm) embedment depth was selected for use in the MGS when located at the slope break point of a 3H:1V fill slope. A 6-ft (1.8-m) long steel guardrail post embedded into a roller-compacted, special MSE wall fill material, driven through the upper wire-mesh layer, and placed at the slope break point, was found to provide adequate post-soil resistance for use in the MGS. In addition, dynamic component testing of steel posts driven at the slope break point did not reveal any concerns for damage to the wire-faced, MSE wall system.

Following the dynamic component testing effort, a non-blocked version of the MGS was developed for use with a wire-faced, MSE wall system. The modified MGS utilized 6-ft (1.8-m) long steel posts spaced on 75 in. (1,905 mm) centers, a top mounting height of 31 in. (787 mm) for the W-beam rail, and steel W-beam backup plates at the steel post locations. The 12-in. (305-mm) deep wood spacer or offset blocks were not utilized in this barrier system.

The non-blocked MGS was successfully crash tested using both the 1100C small car and 2270P pickup truck vehicles according to TL-3 safety performance guidelines provided in MASH, as shown in Table 18. After the first full-scale crash test, the deformed posts were removed from the wire-faced, MSE wall. Subsequently, the soil region surrounding the locations of the damaged posts were filled with soil and recompacted. Then, new steel posts were driven into the wire-faced, MSE wall at the slope break point in order to repair the MGS and for use in the second full-scale crash test. Following both crash tests, no damage was observed in the wire-

faced, MSE wall system for the backside of the steel posts positioned 5 ft -9 in. (1.75 m) away from the MSE wall's outer face.

Based on the research program described herein, the non-blocked MGS (Concept no. 4) is recommended for use on top of wire-faced, MSE walls when the centerline of the steel posts are placed at the slope break point of a 3H:1V fill slope. Under this scenario and as previously shown in Figure 10, the face of the W-beam rail would be positioned approximately 6 ft $-6\frac{1}{4}$ in. (1.99 m) away from the outer edge of the wire-faced, MSE wall when assuming a 2-ft (0.6 m) fill height – 1 ft (0.3 m) normal layer thickness of select wall backfill and 1 ft (0.3 m) thick combined layer for wearing surface and road base material. The current FHLD accepted practice, as depicted in Figure 3, is to install the face of conventional, wood-post W-beam guardrail 9 ft – 71/4 in. (2.93 m) away from the exterior face of the MSE wall when assuming a 2-ft (0.6-m) level surface behind the posts, an adjacent 3H:1V fill slope, and a 2-ft (0.6-m) fill height for the road base and wearing surface. Therefore, the implementation of the new TL-3 barrier system would provide at least a 3 ft - 1 in. (0.94 m) reduction in the required width of the wire-face, MSE wall. Thus, the non-blocked, steel post MGS provides (1) an economical and practical barrier alternative for use on wire-faced, MSE walls, (2) satisfactory vehicle containment under the TL-3 MASH impact conditions, (3) reduces the required width of the wire-faced, MSE wall structure with the elimination of a timber blockout and removal of the 2-ft (0.6-m) wide level terrain behind the posts, and (4) results in decreased construction and material costs for the overall wirefaced, MSE wall and barrier systems.

As noted above, the non-blocked MGS was successfully crash tested with the back side of the steel posts positioned approximately 2 ft – 9 in. (0.84 m) away from the inside edge of the wall facing fill or 5 ft – 9 in. (1.75 m) away from the outer edge of the wire-faced, MSE wall. For this baseline configuration, the steel posts were driven into the select wall backfill. During the 2270P crash test (test no. MGSGW-2), the maximum dynamic barrier deflection was observed to be 35.7 in. (907 mm). In addition, no damage was observed in the MSE wall structure during either of the MASH crash tests. Following the successful crash testing program on the finalized configuration (Concept No. 4), as shown in Figure 10, the researchers believed that the non-blocked MGS should be capable of safely containing and redirecting the 2270P pickup truck under TL-3 impact conditions when positioned closer than the 5-ft 9-in. (1.75-m) lateral offset to the outer edge of the MSE wall.

Due to the presence of the special compaction zone consisting of larger rocks (i.e., wall facing fill), it is impossible to drive steel posts 3 ft (0.91 m) laterally away from the outer MSE wall edge. This assertion comes from field results obtained from the post-soil testing program as well as a general concern for mitigating damage to the MSE wall. Therefore, it was deemed necessary to establish a minimum lateral offset between the backside of the steel posts and the rock boundary (i.e., inside edge of the wall facing fill) to address these concerns. Further, any minimum design guidelines should consider the situation where the wall facing fill width may slightly exceed 3 ft (0.91 m).

Recall, the non-blocked, steel post MGS performed in an acceptable manner when backside face was positioned 2-ft 9 in. (0.84 m) laterally away from the inside face of the wall facing fill. When possible, it would seem reasonable to accommodate this lateral barrier offset. However,

special scenarios will occur in actual field installations in which this lateral barrier offset will not be available. Therefore, the recommended minimum lateral barrier offset should be 1 ft (0.3 m) between the back side of post to inside edge of the wall facing fill or 4 ft (1.22 m) between back side of post to outer edge of the MSE wall, whichever results in greater lateral offset between the post and exterior wall surface. For high-energy, vehicular impact events, this minimum lateral placement recommendation would provide the most economical barrier system and MSE wall configuration, assure adequate safety performance, and mitigate concerns for damage to the MSE wall structure.

For this minimum placement recommendation, the lateral offset between the rail face and outer edge of the MSE wall would be 4 ft - 9½ in. (1.45 m). For varying thicknesses of select wall backfill and different widths for the 3H:1V fill slope, three different configurations were prepared to demonstrate the recommended minimum lateral barrier offset for the steel posts, as shown in Figures 89 through 91. When the non-blocked, steel-post MGS is installed using the minimum lateral barrier offset, the maximum width reduction for the wire-faced, MSE wall would increase from 3 ft - 1 in. (0.94 m) to 4 ft - 10 in. (1.47 m) if compared to the current FLHD guidance, thus providing even greater economic benefit at the TL-3 impact conditions.

As noted above and for TL-3 applications, the non-blocked, steel post MGS was constructed, tested, and evaluated with the front face of the W-beam rail positioned approximately 6 ft $-6\frac{1}{4}$ in. (1.99 m) away from the outer edge of the wire-faced, MSE wall. Based on the successful safety performance evaluations of the two crash tests, the observed dynamic barrier deflections, and the configuration of the MSE wall, the non-blocked MGS can also be installed with the rail face approximately 4 ft - $9\frac{1}{4}$ in. (1.45 m) away from the outer edge of the MSE wall system and still meet TL-3 impact safety standards.

Under TL-2 impact conditions, dynamic rail deflections for the non-blocked MGS would be reduced from those observed under TL-3 impact conditions. As such, the recommended barrier placement for TL-2 conditions could conservatively utilize the minimum lateral barrier offset of $4 \text{ ft} - 9\frac{1}{4} \text{ in.}$ (1.45 m) which was noted for TL-3 conditions. However, TL-2 post deflections near the ground line may be smaller than those deflections observed during comparable TL-3 impact events. As a result and under TL-2 impact conditions, a 6-in. (152-mm) lateral barrier shift toward the outer MSE wall edge may be considered. Under this more aggressive scenario, the rail face would be positioned approximately $4 \text{ ft} - 3\frac{1}{4} \text{ in.}$ (1.30 m) away from the wire-faced, MSE wall. Of course, this modified TL-2 barrier placement could result in increased risk for damage to the MSE wall structure as well as reduced constructability in driving steel posts if the wall facing fill (i.e., layer of larger stones) extends beyond the common width of 3 ft (0.91 m).

The roller-compacted soil fill material and mesh reinforcement within the wire-faced, MSE wall system provided a stiff foundation for the driven, steel guardrail posts. This finding was made upon review of the post-soil responses observed in selected dynamic bogie tests as well as from the barrier deflections and working widths observed during the full-scale crash testing program reported herein. From the successful MASH crash testing program reported herein, it is the researcher's opinion that a non-blocked MGS would also perform satisfactorily when installed in standard soil placed on level terrain. However, the safety performance of a non-blocked MGS installed on level terrain can only be verified through full-scale crash testing.

Previously, it has been demonstrated that wood blockouts used in combination with the MGS greatly increases barrier capacity, reduces occupant risk, and improves the vehicle post-impact trajectory. Thus, the researchers recommend that 12-in. (305-mm) deep wood spacer blocks, or acceptable alternatives, be used with the MGS when the roadside geometry can accommodate a guardrail system with increased width.

Concrete curbs or asphalt dikes often provide drainage control at the edge of roadway or shoulder. Occasionally, curbs and vehicular barrier systems are both required along the roadside. For these circumstances, it is necessary to ensure that the combination curb and guardrail system meets current impact safety standards. Therefore, if curbs are required on MSE wall structures, it is recommended that the steel post MGS be installed with wood blockouts, or other acceptable alternatives.

Mechanical Test Report

mechanical tests are performed on a sample from the tail of a coil rield Strength Tensile Strength % Elongation in 2 inches 64,860 psi 83,230 psi 23.5%

This material has been produced and tested in accordance with each of the following applicable standards: ASTM E 1806-86, ASTM E 415-99a, ASTM A 751-01. ASTM A 370-03a, JIS Z2201:1998, JIS Z 2241:1998. This report certifies that the above test secults are representative of those contained in the records of North Star BlueScope Steel LLC for the material identified in this test report and is intended to comptly with the requirements of the material description. North Star BlueScope Steel LLC for the material identified in this test report and is intended to comptly with the validity of this material to meet specific applications. Any modifications to this certification are provided negative to the star BlueScope Steel LLC, Detail, Ohio. This material was not exposed to Mercury or any alloy which is found at ambient temperature during processing or while in North Star BlueScope Steel LLC (ask, and hot-road from 3.1 reduction ratio), entirely within the U.S.A calculated in accordance with NIST standards and are maintained at a 4.1 ratio in accordance with NIST standards. Uncertainty data is available upon request. Uncertainty calculations are

CERTIFICATE OF COMPLIANCE

AUGUST 4, 2009

MIDWEST MACHINERY & SUPPLY PO Box 81097 LINCOLN, NE 68501

The following material delivered on 8/3/09 on bill of lading number 19477 has been inspected before and after treatment and is in full compliance with applicable Nebraska Department of Roads requirements for southern yellow pine Timber Guardrail Components, preservative treated with Chromated-Copper-Arsenate (CCA-C) to a minimum retention of .60 lbs/cu.ft. The acceptance of each piece by company quality control is indicated by a hammer brand on the end of each piece.

PAGE 35/52 MIDWEST MACHINERY 402-761-3288 06/04/2009 16:36 262 268 2570 CHARTER STEEL SALE 15:05:58

The following statements are applicable to the material described on the front of this Test Reports

- 1. Except as noted, the steel supplied for this order was melted, rolled and processed in the United States. 2. Mercury was not used during the manufacture of this product; nor was the steel contaminated with mercury during processing.
- Unless directed by the customer, there are no welds in any of the coils produced for this order.
 The laboratory that generated the analytical or test results can be identified by the following key:

Carifficate Number	Lab Dode		Laboratory	Address
0358-01	7386	CSMD	Charter Step! Metting Division	1658 Cold Springs Road, Saukville, WJ 53080
0358-02	8171	CSRD/ CSPD	Charler Steel Rolling/ Processing Division	1858 Cold Springs Road, Saukville, WI 53080
0358-03	123633	P4	Charter Steel Ohio Processing Division	8255 US Highway 25, Risingsun, OH 43457
0268-04	125544	OSC	Charter Steel Cleveland	4300 E. 49th St., Cryahoga Heighta, OH 44125-1904
•	. •	44	Subcontracted last performed by laboratory not in Charter Steel system	

When run by a Charter Steel laboratory, the following tests were performed according to the latest revisions of the specifications listed below, as noted in the Charter Steel Laboratory Quality Manual

Tost	Possible Laboratory	Specification
Chemistry Analysis	CSMD	ASTM E415; ASTM E1019
Macroatch	CSMD	ASTM East
Hardenability (Jominy)	OSMD	ASTM ASSE; JIS G0561
Grain Size	CSIND	ASTM EI12
	CSRD/CSPD, P4, CSC	ASTM 58; ASTM A370
	GSRD/CSPD, P4, CSC	ASTM E18; ASTM A370
Microstructure (spheroldization)	CSRD/GSPD, P4	ASTM A892
Cleanliness	CSRD/CSPD, CSC	ASTM 645

Charter Steel has been accredited to perform all of the above tests by the American Association for Laboratory Accreditation (AZLA). These accreditations expire 01/31/07

All other test results associated with a Charler Steel laboratory that appear on the front of this report, if any, were performed according to documented procedures developed by Charler Steel and are not accredited by A2LA.

- 8. The test results on the front of this report are the true values measured on the samples taken from the production for. They do not apply to any other sample.

 7. This test report cannot be reproduced or distributed except in full without the written permission of Charter Steel. The primary customer whose name and address appear on the front of this form may reproduce this test report, subject to the following restrictions:

 a through a distributed only to their customers

 a Both sides of all pages must be reproduced in full

 8. This cartification is given subject to the terms and conditions of sale provided in Charter Steel's acknowledgment (designated by our Purchase Order number) to the customer's purchase order. Both Purchase Order numbers appear on the front page of this Report.

 9. Where the customer has provided a specification, the results on the front of this test report conform to that specification unless otherwise noted on this test report.

APPENDIX B. INSTALLATION GUIDE

The MSE wall installation guide obtained is contained in this appendix.

WELDED WIRE (WWW) and EUREKA REINFORCED SOIL (ERS) M.S.E RETAINING WALLS

Construction Guide

Eureka, California 95503-5711 Local 707.443.5093 Fax 707.443.2891 Toll-Free 800.762.8962

Web: http://www.hilfiker.com email: info@hilfiker.com

Hilifiker M.S.E. Systems are covered by the following patents: Patent no. 4,117,686; 4,329,089; 4,505,621 and others

HILFIKER MSE WALL SYSTEMS

Welded Wire Wall and Eureka Reinforced Soil (E.R.S.)

The Hilfiker MSE System is a composite mechanically stabilized earth structure, designed for strength, durability and ease of construction. The welded wire mats reinforce the backfill, providing the tensile strength to make the compacted soil a stable structure. The superior pullout resistance of the wire mesh potentially allows a wide range of backfill soils. Properly installed, the Hilfiker MSE System is exceptionally strong, resilient and economical.

Backfill should preferably be select granular material with a high frictional strength.

ALWAYS FOLLOW YOUR PROJECT SPECIFICATIONS!

Compaction of the backfill is very important to prevent unanticipated settlement of the wall. Ninety to ninety-five percent compaction is recommended for walls supporting paved roadways, railroads, buildings, mining equipment and other significant loads. If the backfill is not compacted as recommended, settlement will occur, and may distort the wall face.

In addition, the moisture content of

the backfill prior to and during construction shall be uniformly distributed throughout each lift.

The contractor must provide positive drainage and encapsulation of the backfill to insure that it is not saturated with surface and subsurface moisture. If rain is expected, protect the backfill from getting wet. If it does get wet, remove the wet portion and replace it with dry backfill.

Under no circumstances should the use of saturated backfill ever be permitted within the M.S.E. structure. This includes the placement of future landscape irrigation.

Hilfiker MSE Systems can be designed as battered, vertical or cantilever structures. The welded wire mats are easily trimmed or bent, adapting to curves, angles and steps. A Werded Wire Wall can be designed to fit nearly any special site application.

If you have any questions about design, construction or suitability of application, contact Hilfiker Retaining Walls. We will be happy to answer your questions, or design a retaining wall for your project.

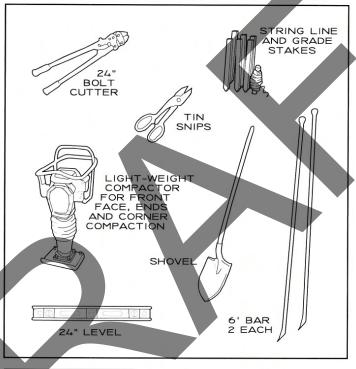

ABOVÉ ALL, PLEASE REMEMBER, THIS BOOKLET IS A GUIDE ONLY. FIELD CONDITIONS NATURALLY VARY. THE OWNER'S DISCRETION AND EXPERIENCE MAY NECESSITATE MODIFICATIONS WITHIN REASON. HILLIKER ASSUMES NO LIABILITY FOR COMPLIANCE, OR LACK THEREOF.

CULVERT THROUGH WALL (CONTINUED)

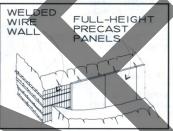

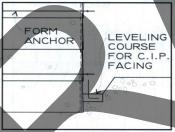

EUREKA REINFORCED SOIL M.S.E. WALL DETAILS

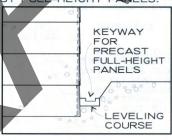

THE HILFIKER E.R.S. WALL BEGINS AS A WELDED WIRE WALL. AFTER COMPLETION AND ANY POTENTIAL SETTLEMENT, PERMANENT FACING IS INSTALLED. THIS MAY CONSIST OF CAST-IN-PLACE CONCRETE, OR FULL-HEIGHT PRECAST CONCRETE PANELS. THE PROJECT CONSTRUCTION PLANS WILL GIVE MORE SPECIFIC DETAILS.

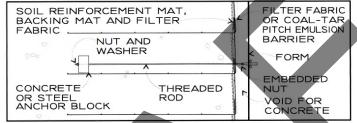

A LEVELING COURSE IS CAST AGAINST THE TOE OF THE WELDED WIRE WALL. THIS WILL SERVE TO SUPPORT AND ALIGN THE FORMS FOR THE C.1.P. FACING, OR WILL HAVE A KEYWAY FOR ALIGNMENT AND CONTROL OF THE TOE OF THE PRECAST FULL HEIGHT PANELS.

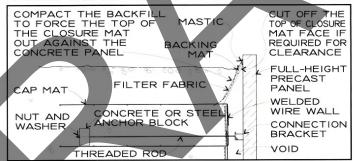

ANCHORS FOR C.I.P. FORMS ANCHORAGE BOLTS ARE INSTALLED AS THE WELDED WIRE WALL IS BUILT. THE DESIGN MAY VARY FROM THAT SHOWN HERE. SPACING, SIZE AND PROJECT-SPECIFIC DETAILS OF

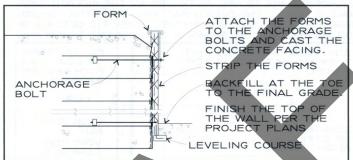

THE ANCHORS WILL BE SHOWN IN THE CONSTRUCTION PLANS.

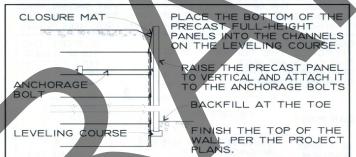

ANCHORS FOR FULL-HEIGHT PRECAST PANELS ANCHORAGE BOLTS ARE INSTALLED ONLY NEAR THE TOP OF THE WALL. THE DESIGN MAY VARY FROM THAT SHOWN HERE. SPACING, SIZE AND PROJECT-SPECIFIC DETAILS OF THE ANCHORS WILL BE SHOWN IN THE CONSTRUCTION PLANS.

FINISHING THE E.R.S. C.I.P. FACING

FINISHING THE E.R.S. PRECAST FACING

STAND BACK AND ADMIRE YOUR WORK OF ART! SEND PHOTOGRAPHS TO HILFIKER RETAINING WALLS FOR POTENTIAL PUBLICATION (WITH YOUR APPROVAL, OF COURSE!)

FOR MORE INFORMATION ON WELDED WIRE REINFORCEMENT (WWR) CHECK THE WEBSITE FOR THE WIRE REINFORCEMENT INSTITUTE: HTTP://www.wirereinforcementinstitute.org/

OTHER HILFIKER PRODUCTS

ArtWeld Gabions are factory-assembled of galvanized 9 or 11 ga Welded Wire Mesh, and are shipped folded flat. Standard sizes are available, and non-standard sizes can be supplied. The mesh can be field-cut to any size or shape without losing structural strength. In comparison to conventional gabions, the larger wire diameter and welded grid gives greater strength, longer life and easier installation. "Spiral" binders, used in field assembly of the gabion edges, and preformed stiffeners, are fast and simple to install.

STEEPENED SLOPE

The Hilfiker Steepened slope system is composed of Welded Wire Fabric components. The flat primary soil reinforcement mats are interlocked with bent facing mats, prefabricated to a 1:1 slope. The slope may be flattened, if desired, by stepping each layer back. Behind the facing mats are Welded Wire Fabric backing mats incorporated with erosion mat or sod. Virtually any type of sod or vegetation that will best suit the environment may be used with this system. Low-growth, maintenance-free vegetation is typically specified.

ARTWELD GABIONS

REINFORCED SOIL EMBANKMENT (SMOOTH FACE)

The R.S.E. Smooth Face Retaining Wall retains most of the advantages of the Welded Wire Wall, while providing the additional durability of precast face panels. Panels can be cast to match a variety of architectural treatments, as well as a smooth finish. In most structures, the simple 12.5' x 2.5' standard panel is used, making all the panels interchangable. We also manufacture special panel sizes when required. Panels are cast with a cartilever footing at the back, and pre-installed reinforcement mat anchors, making installation fast and easy.

SPIRALNAIL WALL SYSTEM

The Spiralnail system was originally designed to replace conventional soil nailing systems. Spiralnails are driven directly into the soil, eliminating time-consuming 'dail' and grout'. They can be used in a variety of projects, including retaining walls, slope stabilization, tie-backs for cast-in-place or precast concrete panels, repair of existing retaining structures, and can be designed to act as soil drains. They can also be faced with welded wire, gabions, and "spider" slope reinforcing.

APPENDIX C. VEHICLE CENTER OF GRAVITY DETERMINATION

The information used to determine the center of gravity of each vehicle and documentation of the ballast placed in each vehicle is shown in this appendix.

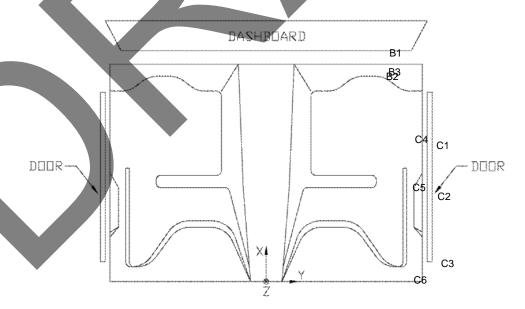

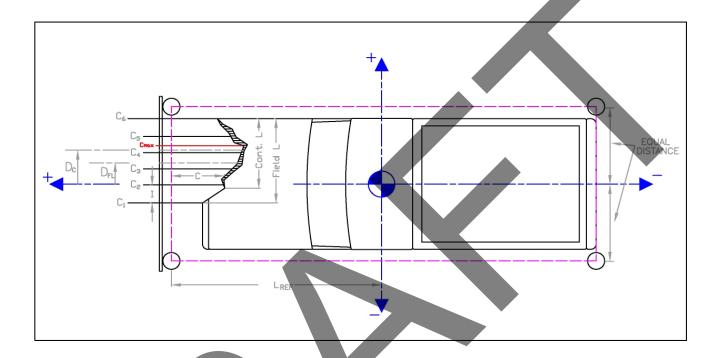

Figure 144. Chart. Occupant Compartment Deformation Data, Test No. MGSGW-2.

 Date:
 11/23/2009
 Test Number:
 MGSGW-2

 Make:
 Dodge
 Model:
 2270P (RAM 1500)
 Year:
 2003

	in.	(mm)
Distance from C.G. to reference line - L _{REF} :	113	(2870)
Width of contact and induced crush - Field L:	39	(991)
Crush measurement spacing interval (L/5) - I:	7.8	(198)
Distance from center of vehicle to center of Field L - D _{FL} :	19.5	(495)
Width of Contact Damage:	18	(457)
Distance from center of vehicle to center of contect damage - D _C :_	28.5	(724)

NOTE: Enter "NA" for crush measurement if distance can not be measured (i.e., side of vehicle has been pushed inward)
