16. Abstract The objective of this study	was to adapt and evaluate a weak-po	ost, W-beam guardrail system for use within mow strips and

The objective of this study was to adapt and evaluate a weak-post, W-beam guardrail system for use within mow strips and other pavements. The weak-post guardrail system was originally designed as the MGS bridge rail and has also been adapted for use on culverts. It was envisioned that the weak-post design would absorb the impact forces and prevent damage to the mow strips, thereby minimizing maintenance and repair costs.

Evaluation of the weak posts in mow strips began with three rounds of dynamic bogie testing. Round 1 of bogie testing showed that 4-in. (102-mm) thick concrete would sustain only minor spalling from impacts to the posts. However, the posts would push through 4-in. and 6-in. (102-mm and 152-mm) thick asphalt mow strips. During Round 2, 24-in. (610-mm) long, 4-in. x 4-in. (102-mm x 102-mm) sockets with 10-in. x 9-in (254-mm x 229-mm) shear plates were utilized to better distribute the impact load to the asphalt pavement and prevent damage. However, Round 3 of bogie testing consisted of dual-post impacts, and the asphalt suffered from shear block fracture between the two 24-in. (610-mm) sockets and the back edge of the mow strip. A dual-post test within a 4-in. (102-mm) thick concrete pad showed only minor spalling.

A full-scale MASH 3-11 test was conducted on the weak-post guardrail system installed within an asphalt mow strip. Due to the Round 3 testing results, the asphalt thickness was increased to 6 in. (152 mm), and the socket depth was increased to 30 in. (762 mm). The 2270P pickup was contained and safely redirected, and all MASH safety criteria were satisfied. Unfortunately, the asphalt fractured, and a 2½-in. (64-mm) wide crack ran from socket to socket throughout the impact region of the system. Therefore, the weak-post guardrail system was crashworthy, but would require repairs in its current configuration. The system could also be installed in a concrete mow strip to prevent pavement damage.

17. Document Analysis/Descriptors Highway Safety, Crash Test, W-beam, Guardrail, Weak Posts, MASH, Test Level 3, Mow Strip, Asphalt, Concrete, and Component Testing		 Availability Statement No restrictions. Document available from: National Technical Information Services, Springfield, Virginia 22161

DISCLAIMER STATEMENT

This report was completed with funding from the Federal Highway Administration, U.S. Department of Transportation and the Midwest States Regional Pooled Fund Program. The contents of this report reflect the views and opinions of the authors who are responsible for the facts and the accuracy of the data presented herein. The contents do not necessarily reflect the official views or policies of the state highway departments participating in the Midwest States Regional Pooled Fund Program nor the Federal Highway Administration, U.S. Department of Transportation. This report does not constitute a standard, specification, regulation, product endorsement, or an endorsement of manufacturers.

UNCERTAINTY OF MEASUREMENT STATEMENT

The Midwest Roadside Safety Facility (MwRSF) has determined the uncertainty of measurements for several parameters involved in standard full-scale crash testing and non-standard testing of roadside safety features. Information regarding the uncertainty of measurements for critical parameters is available upon request by the sponsor and the Federal Highway Administration.

INDEPENDENT APPROVING AUTHORITY

The Independent Approving Authority (IAA) for the data contained herein was Dr. Cody Stolle, Research Assistant Professor.

ACKNOWLEDGEMENTS

The authors wish to acknowledge several sources that made a contribution to this project: (1) the Midwest States Regional Pooled Fund Program funded by the Illinois Department of Transportation, Indiana Department of Transportation, Iowa Department of Transportation, Kansas Department of Transportation, Minnesota Department of Transportation, Missouri Department of Transportation, Nebraska Department of Roads, New Jersey Department of Transportation, Ohio Department of Transportation, South Dakota Department of Transportation, Wisconsin Department of Transportation, and Wyoming Department of Transportation for sponsoring this project; (2) MwRSF personnel for constructing the barriers and conducting the crash tests; and (3) the Mid-America Transportation Center.

Acknowledgement is also given to the following individuals who made a contribution to the completion of this research project.

1 INTRODUCTION

1.1 Background

Over the years, it has become desirable to place a longitudinal concrete slab or continuous asphalt pavement under W-beam guardrail systems in order to reduce the time and costs for mowing operations around guardrail posts. Unfortunately, prior research has demonstrated that standard strong-post W-beam guardrails may not perform in an acceptable manner when the guardrail posts are placed directly in an asphalt or concrete pavement that restricts post rotation. Rail ruptures have been attributed to a loss of energy dissipation in the barrier system when posts were restricted from rotating through the soil [1-2].

Currently, guardrail posts installed within mow strips have required a blocked-out area or "leave-out" that surrounds each post. Leave-outs allow posts to rotate through the soil, which results in acceptable safety performances for standard W-beam guardrails [3-6]. Many leave-out designs incorporate weak cement, grout mixes, or rubber/foam pads that restrict plant growth but crumble away under impact loads. After an impact event, the debris is removed, soil is retamped, a new post is driven into place, and a new batch of the weak cement/grout is poured into the leave-out. Therefore, significant effort is required to reset a post after an impact. Examples of typical grout-filled leave-outs before and after impact are shown in Figure 1.

In 2010, the Midwest Guardrail System (MGS) Bridge Rail was developed utilizing S3x5.7 (S76x8.5) steel posts at half-post spacing, or 37¹/₂ in. (953 mm) on center, to support standard W-beam guardrail segments [7-8]. The posts were installed in tubular steel sockets that were side-mounted to a concrete bridge deck, as shown in Figure 2. Energy was dissipated during impact events through bending of the weak posts instead of post rotation through soil. The MGS bridge rail was successfully crash tested to the Teat Level 3 (TL-3) safety performance standards of the *Manual for Assessing Safety Hardware* (MASH) [9].

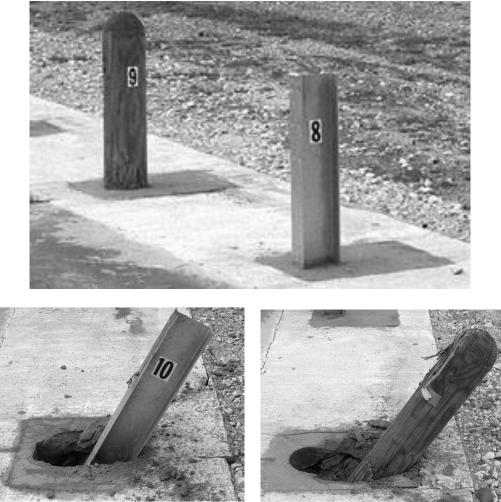

Figure 1. Pre- and Post-Test Photos of Posts in Grout-Filled Leave-Outs [3]

Figure 2. MGS Bridge Rail Installation

Since the MGS bridge rail posts were installed in rigid sleeves, it was believed that the MGS Bridge Rail could be adapted for use in guardrail applications where mow strips similarly restrict the movement of the posts below the groundline. Ideally, this application would eliminate the need for leave-outs around guardrail posts installed in unyielding pavements. Additionally, the use of sockets would minimize costs and labor time during installation and repairs to damaged posts.

1.2 Objective

The objective of this research effort was to adapt the weak-post, MGS bridge rail for use in mow strips and other pavements. Ideally, the steel guardrail system components would withstand the impact loads and dissipate enough energy to leave the mow strip undamaged. Thus, system repairs would require only the removal and replacement of damaged barrier components (posts and rail segments). The new guardrail system was to be evaluated according to MASH TL-3 safety performance criteria.

1.3 Research Approach

The project was completed via a series of tasks. First, a review of multiple Departments of Transportation (DOTs) standards was conducted to determine typical mow strip widths, thicknesses, and materials (concrete or asphalt), and to select a critical mow strip configuration for testing. Next, dynamic component testing was conducted to evaluate pavement damage resulting from impacts into posts with various socket configurations. Based on the component testing results, a design configuration was selected and full-scale crash tested according to MASH TL-3 conditions. Finally, conclusions and recommendations were formed concerning the final system design and installation practices.

2 REVIEW OF MOW STRIP STANDARDS AND PRACTICES

Before the MGS bridge rail could be adapted for use in mow strips, it was vital to identify the mow strip configurations currently being installed. Of specific importance to this project were the thicknesses, widths, and pavement materials of typical mow strip installations, as these characteristics determine the strength of a mow strip. Therefore, a review was conducted on the mow strip standards from the various members of the Midwest States Pooled Fund Program. The results of this review are summarized in Table 1.

Stote DOT	Typical Mow Strip Configuration			
State DOT	Material	Thickness	Width	
Wisconsin	Asphalt	4 in. 4 ft		
South Dakota	Asphalt	>4 in. 4 ft		
Iowa	Asphalt	4 in. 4 ft		
Wyoming	Asphalt	4 in. 3 ft		
New Jersey	Asphalt	4–6 in.	>2 ft	
Missouri	Asphalt	3–4 in. 4 ft		
Nebraska	Asphalt	4 in. 4 ft		
Illinois	Concrete Asphalt	4 in. 4 ft 4 in. 4 ft		
Ohio	Concrete Asphalt	4 in. 4 ft 3–4 in. 4 ft		
Kansas	Concrete	4 in.	4 ft	

Table 1. Typical Mow Strip Configurations of Pooled Fund Members

From the ten State Departments of Transportation (DOTs) that participated in the review, nine installed asphalt mow strips, while three installed concrete mow strips (two states used both). Thicknesses were reported between 3 to 6 in. (76 to 152 mm), although 4 in. (102 mm) was the most commonly utilized thickness. Typical mow strip widths were consistently reported as 4 ft (1.2 m), with only two states allowing narrower mow strips.

The results of this review indicated that a 4-in. (102-mm) thick, 4-ft (1.2-m) wide asphalt mow strip was the most commonly utilized configuration. Therefore, it was desired for the weakpost guardrail system to be compatible with 4-in. (102-mm) thick, 4-ft (1.2-m) wide asphalt mow strips. However, through discussions with the project sponsors, other mow strip configurations would be acceptable if stronger mow strips were necessary to prevent damage. As such, the use of asphalt thicknesses up to 6 in. (152 mm) and/or the use of concrete as the pavement material were also options for the mow strip design. Dynamic component testing would be conducted to evaluate the mow strip configurations and determine the required strength to prevent pavement damage.

3 COMPONENT TESTING CONDITIONS

3.1 Purpose

One of the objectives for the new guardrail system was to prevent damage to the mow strip, thereby minimizing repair time and costs. As such, it was important to quantify the expected level of damage that various mow strip configurations would incur while supporting S3x5.7 (S76x8.5) guardrail posts. Dynamic component testing was conducted to evaluate various mow strips and aid in the selection of the final system design configuration.

3.2 Scope

Dynamic component testing was conducted with a bogie vehicle impacting an S3x5.7 (S76x8.5) post installed within concrete and asphalt mow strips of various widths. Additionally, some of the tests utilized steel sockets of varying depths to support the posts. Altogether, 11 component tests were conducted over three rounds of component testing. The tests were conducted on an iterative basis in order to determine the minimum size and strength of a mow strip to prevent damage during vehicle impacts to the weak-post guardrail system.

3.3 Equipment and Instrumentation

Equipment and instrumentation utilized to collect and record data during the dynamic bogie tests included a bogie vehicle, accelerometers, a retroreflective speed trap, high-speed and standard-speed digital video, and still cameras.

3.3.1 Bogie Vehicle

A rigid-frame bogie was used to impact the posts. A variable-height, detachable impact head was used in the testing. The bogie head was constructed of $2\frac{1}{2}$ -in. x $2\frac{1}{2}$ -in. (64-mm x 64-mm), $\frac{5}{16}$ -in. (8-mm) thick square steel tubing, with $\frac{3}{4}$ -in. (19-mm) neoprene belting attached to the front of the head to prevent local damage to the post from the impact. The impact head was bolted to the bogie vehicle, creating a rigid frame with an impact height of 12 in. (305 mm),

which was selected to simulate the bumper height of a small car. The bogie with the impact head is shown in Figure 3. The weight of the bogie with the addition of the mountable impact head and accelerometers was approximately 1,800 lb (820 kg).

Figure 3. Rigid-Frame Bogie on Guidance Track

The tests were conducted using a steel corrugated beam guardrail to guide the tire of the bogie vehicle. A pickup truck was used to push the bogie vehicle to the required impact velocity. After reaching the target velocity, the push vehicle braked, allowing the bogie to be free-rolling as it came off the track. A remote braking system was installed on the bogie, allowing it to be brought safely to rest after the test.

3.3.2 Accelerometers

During each component test, an accelerometer system was mounted on the bogie vehicle near its center of gravity to measure accelerations in the longitudinal, lateral, and vertical directions. However, only the longitudinal acceleration was processed and reported. The electronic accelerometer data obtained in dynamic testing was filtered using the SAE Class 60 and the SAE Class 180 Butterworth filters conforming to SAE J211/1 specifications [10]. Four different accelerometer systems were utilized throughout the component testing program. Table 2 contains a breakdown of the accelerometers utilized during each component test.

Round of	Test No	Accelerometers			
Testing	Test No.	SLICE-1	SLICE-2	DTS	EDR-3
	MS-1	X			Х
1	MS-2	Х			Х
1	MS-3	X			Х
	MS-4	X			Х
	MS-5			Х	Х
	MSSP-1		Х		
2	MSSP-2		X		
	MSSP-3		X		
	MSSP-4		X		
3	MSSP-5		X		
3	MSSP-6		X		

Table 2. Accelerometers Utilized during Each Component Test

The first two systems, the SLICE-1 and SLICE-2 units, were modular data acquisition systems manufactured by Diversified Technical Systems, Inc. (DTS) of Seal Beach, California. The acceleration sensors were mounted inside the bodies of custom-built SLICE 6DX event data recorders and recorded data at 10,000 Hz to the onboard microprocessor. Each SLICE 6DX was configured with 7 GB of non-volatile flash memory, a range of \pm 500 g's, a sample rate of 10,000 Hz, and a 1,650 Hz (CFC 1000) anti-aliasing filter. The "SLICEWare" computer software program and a customized Microsoft Excel worksheet were used to analyze and plot the accelerometer data.

The third accelerometer system was a two-arm piezoresistive accelerometer system manufactured by Endevco of San Juan Capistrano, California. Three accelerometers were used to measure each of the longitudinal, lateral, and vertical accelerations independently at a sample rate of 10,000 Hz. The accelerometers were configured and controlled using a system developed

and manufactured by DTS. More specifically, data was collected using a DTS Sensor Input Module (SIM), Model TDAS3-SIM-16M. The SIM was configured with 16 MB SRAM and eight sensor input channels with 250 kB SRAM/channel. The SIM was mounted on a TDAS3-R4 module rack. The module rack was configured with isolated power/event/communications, 10BaseT Ethernet and RS232 communication, and an internal backup battery. Both the SIM and module rack were crashworthy. The "DTS TDAS Control" computer software program and a customized Microsoft Excel worksheet were used to analyze and plot the accelerometer data.

The fourth system, Model EDR-3, was a triaxial piezoresistive accelerometer system manufactured by Instrumented System Technology (IST) of Okemos, Michigan. The EDR-3 was configured with 256 kB of RAM, a range of ± 200 g's, a sample rate of 3,200 Hz, and a 1,120 Hz low-pass filter. The "DynaMax 1 (DM-1)" computer software program and a customized Microsoft Excel worksheet were used to analyze and plot the accelerometer data.

At the time of testing, the EDR-3 transducer was not calibrated to ISO 17025 standards, due to the lack of an ISO 17025 calibration laboratory with the capabilities of calibrating the unit. However, the EDR-3 was calibrated by IST, which provided traceable documentation for the calibration. MwRSF also recognizes that the EDR-3 does not satisfy the 10,000 Hz sample frequency recommended by MASH. Following numerous test comparisons, the EDR-3 has been shown to provide equivalent results to the DTS unit, which does satisfy MASH criteria and has ISO 17025 calibration traceability. Therefore, MwRSF has continued to use the EDR-3 as a backup device during physical impact testing.

3.3.3 Retroreflective Optic Speed Trap

The retroreflective optic speed trap was used to determine the speed of the bogie vehicle before impact. Three retroreflective targets, spaced at approximately 18-in. (457-mm) intervals, were applied to the side of the vehicle. When the emitted beam of light was reflected by the targets and returned to the Emitter/Receiver, a signal was sent to the data acquisition computer, recording at 10,000 Hz, as well as the external LED box activating the LED flashes. The speed was then calculated using the spacing between the retroreflective targets and the time between the signals. LED lights and high-speed digital video analysis are only used as a backup in the event that vehicle speeds cannot be determined from the electronic data.

3.3.4 Digital Photography

At a minimum, one AOS high-speed digital video camera, one GoPro digital video camera, and one JVC digital camera were used to document each test. The AOS high-speed camera had a frame rate of 500 frames per second, the GoPro video camera had a frame rate of 120 frames per second, and the JVC digital video camera had a frame rate of 29.97 frames per second. The cameras were typically placed laterally from the post, with a view perpendicular to the bogie's direction of travel. A Nikon D50 digital still camera was used to document pre- and post-test conditions for all tests.

3.4 End of Test Determination

When the impact head initially contacted the test article, the force exerted by the surrogate test vehicle was directly perpendicular. However, as the post rotated, the surrogate test vehicle's orientation and path moved farther from perpendicular. This introduced two sources of error: (1) the contact force between the impact head and the post had a vertical component and (2) the impact head slid upward along the test article. Therefore, only the initial portion of the accelerometer trace is typically used, since variations in the data become significant as the system rotates and the surrogate test vehicle overrides the system. Additionally, guidelines were established to define the end-of-test time using the high-speed video of the impact. The first occurrence of either of the following events was used to determine the end of the test: (1) the test article fractures or (2) the surrogate vehicle overrides/loses contact with the test article.

3.5 Data Processing

The electronic accelerometer data obtained in dynamic testing was filtered using the SAE Class 60 Butterworth filter conforming to the SAE J211/1 specifications [10]. The pertinent acceleration signal was extracted from the bulk of the data signals. The processed acceleration data was then multiplied by the mass of the bogie to get the impact force using Newton's Second Law. Next, the acceleration trace was integrated to find the change in velocity versus time. Initial velocity of the bogie, calculated from the speed trap data, was then used to determine the bogie velocity, and the calculated velocity trace was integrated to find the bogie's displacement. This displacement was also the displacement of the post. Combining the previous results, a force vs. deflection curve was plotted for each test. Finally, integration of the force vs. deflection curve provided the energy vs. deflection curve for each test.

4 COMPONENT TESTING – ROUND 1

4.1 Purpose

The original MGS bridge rail system utilized 4-in. x 4-in. (102-mm x 102-mm) steel tube sockets to support the S3x5.7 (S76x8.5) posts to the bridge deck. The sockets were designed to be rigid and prevent movement of the posts below the groundline during impacts. However, it was unclear if sockets would be necessary for these posts installed in mow strips, as the concrete/asphalt may have enough strength to prevent movement of the posts at the groundline. To explore this possibility, Round 1 of component testing was conducted to evaluate the damage associated with both asphalt and concrete mow strips without sockets.

4.2 Scope

Round 1 of component testing consisted of four tests on S3x5.7 (S76x8.5) posts installed within various mow strips without sockets, as shown in Figures 4 through 6. Test nos. MS-1 and MS-3 were conducted with the posts installed with a 4-in. (102-mm) thick concrete mow strip, test no. MS-2 was conducted with a 4-in. (102-mm) thick asphalt mow strip, and test no. MS-4 was conducted with a 6-in. (152-mm) thick asphalt mow strip. For Test MS-1, the post was installed through a 4-in. x 4-in. (102-mm x 102-mm) leave-out formed in the concrete during casting of the mow strip, while the post for MS-3 was installed through a 4-in. (102-mm) diameter hole cored in the concrete. The posts for MS-2 and MS-4 were driven through the asphalt and into the ground without any holes or leave-outs in the pavement. All mow strips were 4 ft (1.2 m) wide, and the posts were installed at the center of the mow strip width.

The unreinforced concrete mow strip was constructed from a concrete mix with a compressive strength of 4,000 psi (28 MPa). The asphalt mow strip was constructed from a 52-34 grade binder typically utilized in highway shoulder construction in Nebraska. The S3x5.7 (S76x8.5) posts were designated as A36 steel. However, the posts were fabricated from a 50 ksi

(345 MPa) steel that also satisfied A992 requirements. This increased strength resulted in a more critical evaluation of the mow strips. Material specifications, mill certifications, and certificates of conformity for the installation materials are shown in Appendix A.

The bogie vehicle impacted the posts at a height of 12 in. (305 mm), a targeted impact speed of 20 mph (32 km/h), and an angle of 90 degrees, thus causing strong-axis bending. This impact condition was selected to provide a critically high load to the post and the supporting mow strip. The same impact conditions were used previously when evaluating the adaptation of the MGS bridge rail for use on culvert headwalls [11]. The complete test matrix for Round 1 of component testing is shown in Table 3.

Table 3. Component	Testing Matrix,	Round 1
--------------------	-----------------	---------

	Mow Strip				Impact	Impact	Impact	
Test No.	Material	Thickness in. (mm)	Width ft (m)	Installation Hole	Height in. (mm)	Speed mph (km/h)	Angle Deg.

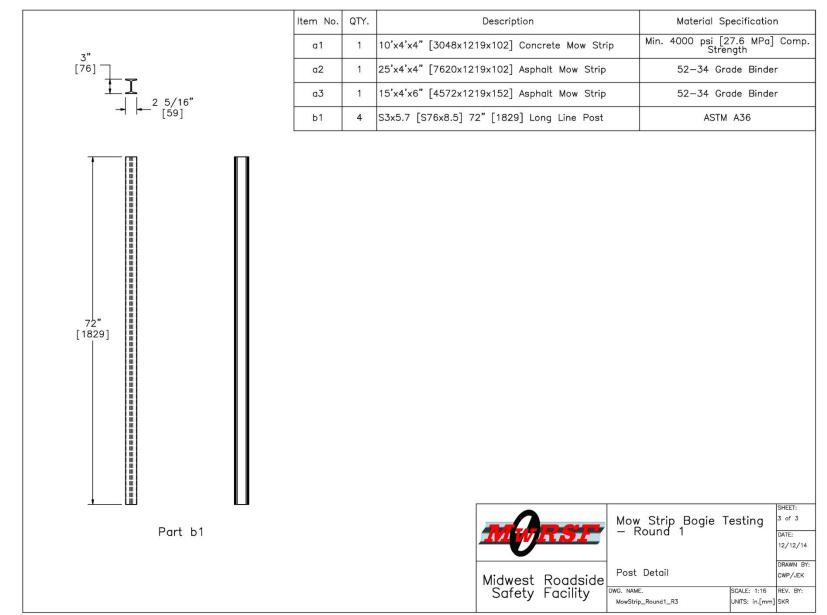

Figure 6. Post Details and Bill of Materials, Component Testing Round 1

4.3 Results

Through component testing, the performance of each mow strip configuration was evaluated in terms of both structural integrity and resistance force. Mow strips would be deemed adequate if no damage was sustained during the impact event, allowing quick and easy repair of the system. Additionally, accelerometer data for each test was processed to obtain acceleration, velocity, and deflection data, as well as force vs. deflection and energy vs. deflection curves. Although the individual transducers produced similar results, the values described herein were calculated from the SLICE data curves in order to provide a common basis for comparing results from multiple tests. Test results for all transducers are provided in Appendix B.

4.3.1 Test No. MS-1

Test no. MS-1 was conducted on July 17, 2013 at approximately 11:00 a.m. The weather conditions, per the National Oceanic and Atmosphere Administration (station 14939/LNK), were reported and are shown in Table 4.

Temperature	88° F
Humidity	47%
Wind Speed	9 mph
Wind Direction	210° From True North
Sky Conditions	Sunny
Visibility	10 Statute Miles
Pavement Surface	Dry
Previous 3-Day Precipitation	0.0 in.
Previous 7-Day Precipitation	0.0 in.

Table 4. Weather Conditions, Test No. MS-1

During test no. MS-1, the bogie impacted the S3x5.7 (S76x8.5) steel post at a speed of 19.7 mph (31.7 km/h) and an angle of 90 degrees, causing strong-axis bending in the post. By 0.008 sec after impact, a plastic hinge had formed in the post at groundline. The post continued to bend backward until the bogie head overrode the top of the post 0.121 sec after impact.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 7. Upon impact, the resistance force increased rapidly to a peak force of 14.5 kips (64.5 kN) at a displacement of 1.1 in. (28 mm). The force remained above 10 kips (4.5 kN) for the next 5 in. (127 mm) of displacement. By 0.030 sec and a displacement of 10 in. (254 mm), the bogie head was sliding up the post as it bent over, resulting in a reduction of force. Subsequently, the resistance force oscillated below 8.5 kips (37.8 kN) until the bogie head overrode the post at a displacement of 34.0 in. (864 mm). At this deflection, 122.5 k-in. (13.8 kJ) of energy was dissipated.

Damage to the test article consisted of plastic bending of the post at the groundline and minimal surface spalling at the back edge of the concrete hole. The spalling was less than ¹/₄ in. (6 mm) deep, and cracking was not evident. The post was removed without causing further damage. Thus, a new post could be installed without repairs to the concrete. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 8 and 9, respectively.

4.3.2 Test No. MS-2

Test no. MS-2 was conducted on July 17, 2013 at approximately 12:00 p.m. The weather conditions, per the National Oceanic and Atmosphere Administration (station 14939/LNK), were reported and are shown in Table 5.

Temperature	90° F
Humidity	42%
Wind Speed	9 mph
Wind Direction	210° From True North
Sky Conditions	Sunny
Visibility	10 Statute Miles
Pavement Surface	Dry
Previous 3-Day Precipitation	0.0 in.
Previous 7-Day Precipitation	0.0 in.

Table 5. Weather Conditions, Test No. MS-2

During test no. MS-2, the bogie impacted the S3x5.7 (S76x8.5) steel post at a speed of 19.4 mph (31.2 km/h) and an angle of 90 degrees, causing strong-axis bending in the post. By 0.006 sec after impact, a plastic hinge had formed in the post at the groundline. The post continued to bend backward until the bogie head overrode the top of the post 0.128 sec after impact.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 10. Upon impact, the resistance force increased rapidly to a peak force of 12.1 kips (53.8 kN) at a displacement of 1.8 in. (46 mm). The force remained above 10 kips (4.5 kN) through a displacement of 9.8 in. (249 mm). At 0.032 sec and a displacement of 10 in. (254 mm), the bogie head was sliding up the post as it bent over, resulting in a reduction of force. Subsequently, the resistance force oscillated below 5 kips (22.2 kN) until the bogie head

overrode the post at a displacement of 34.0 in. (864 mm). At this deflection, 134.2 k-in. (15.2 kJ) of energy was dissipated.

Damage to the test article consisted of plastic bending of the post at the groundline and displacement and spalling of the asphalt. The post displaced backward approximately 2.5 in. (64 mm) into the asphalt mow strip, which caused displacement and spalling of the asphalt. Removal of the post caused further spalling and cracking to the asphalt. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 11 and 12, respectively.

Previous 3-Day Precipitation	0.72 in.		
Previous 7-Day Precipitation	0.72 in.		

Table 6. Weather Conditions, Test No. MS-3

During test no. MS-3, the bogie impacted the S3x5.7 (S76x8.5) steel post at a speed of 20.8 mph (33.5 km/h) and an angle of 90 degrees, causing strong-axis bending in the post. By 0.006 sec after impact, a plastic hinge had formed in the post at the groundline. The post continued to bend backward until the bogie head overrode the top of the post 0.109 sec after impact.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 13. Upon impact, the resistance force increased rapidly to peaks of 13.9 kips (61.8 kN) and 14.7 kips (65.4 kN) at displacements of 1.2 in. (30 mm) and 6.9 in. (175 mm), respectively. At 0.030 sec and a displacement of 10 in. (254 mm), the bogie head was sliding up the post as it bent over, resulting in a reduction of force. Subsequently, the resistance force oscillated below 6 kips (26.7 kN) until the bogie head overrode the post at a displacement of 32.3 in. (820 mm). At this deflection, 132.8 k-in. (15.0 kJ) of energy was dissipated.

Damage to the test article consisted of plastic bending of the post at the groundline and some surface spalling at the back edge of the concrete hole. However, the spalling was less than ¹/₄ in. (6 mm) deep, and cracking was not evident. The post was removed without causing further damage, so a new post could be installed without repairs to the concrete. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 14 and 15, respectively.

Previous 3-Day Precipitation	0.72 in.		
Previous 7-Day Precipitation	0.72 in.		

Table 7. Weather Conditions, Test No. MS-4

During test no. MS-4, the bogie impacted the S3x5.7 (S76x8.5) steel post at a speed of 23.8 mph (38.3 km/h) and an angle of 90 degrees, causing strong-axis bending in the post. By 0.008 sec after impact, a plastic hinge had formed in the post at the groundline. The post continued to bend backward until the bogie head overrode the top of the post 0.088 sec after impact.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 16. Upon impact, the resistance force increased rapidly to 13.9 kips (61.8 kN) at a displacement of 1.8 in. (46 mm). The force remained above 8 kips (35kN) until reaching a peak force of 14.2 kips (63.2 kN) at a displacement of 11.5 in. (292 mm). At 0.028 sec and a displacement of 12 in. (305 mm), the bogie head was sliding up the post as it bent over, resulting in a reduction of force. Subsequently, the resistance force oscillated below 5 kips (22.2

kN) until the bogie head overrode the post at a displacement of 31.4 in. (798 mm). At this deflection, 155.2 k-in. (17.5 kJ) of energy was dissipated.

Damage to the test article consisted of plastic bending of the post at the groundline and displacement and spalling of the asphalt. The post translated backward approximately 2 in. (51 mm) into the asphalt mow strip, which caused displacement and spalling of the asphalt. Removal of the post caused further spalling and cracking in the asphalt. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 17 and 18, respectively.

4.4 Discussion

The results from Round 1 of dynamic component testing are summarized in Table 8, and force vs. displacement and energy vs. displacement comparisons for all four tests are shown in Figures 19 and 20, respectively. The results from these four tests were similar in terms of resistance forces, absorbed energy, and post behavior, as a plastic hinge formed in the post at the groundline during each test. However, the damage sustained by the mow strips was dependent upon the mow strip material. The concrete mow strips remained intact and sustained only minor spalling along the back edges of the post holes. Both post hole types, the 4-in. x 4-in. (102-mm x 102-mm) leave-out and the 4-in. (102-mm) diameter cored hole, performed similarly, and repairs to the concrete mow strip would not be necessary during replacement of damaged system posts.

Damage to the asphalt mow strips was more prominent than the concrete mow strips, as the posts translated backward at least 2 in. (51 mm) through both the 4-in. and 6-in. (102-mm and 152-mm) thick asphalt mow strips. This displacement caused spalling and cracking that would likely require repairs after impact events. Further asphalt damage occurred when the damaged posts were removed. Therefore, asphalt mow strips were susceptible to permanent damage when guardrail posts were driven directly into the pavement.

The resistance forces recorded during all four of these tests were very similar, with peak forces between 12 and 15 kips (53 and 67 kN). Additionally, significant drops in force between 9 and 12 in. (229 and 305 mm) of displacement correlated to the times when the bogie head began to slide up the posts as they bent over. As a result, the energy absorbed during the tests was very similar, especially over the first 10 to 15 in. (254 to 381 mm) of deflection. Only small differences in forces could be seen between the concrete and asphalt mow strips. The concrete mow strips tended to be slightly stiffer, as they created higher initial peaks through the first 7 in. (178 mm) of displacement. This behavior may be a result of the posts translating through the

asphalt mow strips during the first parts of test nos. MS-2 and MS-4, while the concrete prevented post translation at the groundline in test nos. MS-1 and MS-3.

From these results, a 4-in. (102-mm) thick unreinforced concrete mow strip was shown to be strong enough to support the guardrail posts without sustaining significant damage during impacts. Unfortunately, asphalt mow strips up to 6 in. (152 mm) thick proved too weak to prevent damage and would require repairs. The addition of some type of load-distribution mechanism may be necessary to prevent damage from occurring to asphalt mow strips. This idea was explored in Round 2 of bogie testing.

Test	Mow	Strip	Impact	Impact Velocity	Impact VelocityPeak Force kips 			Total Energy	Mow Strip Damage
No.	Material	Thickness in. (mm)	Angle deg.	mph			@15"	Absorbed k-in. (kJ)

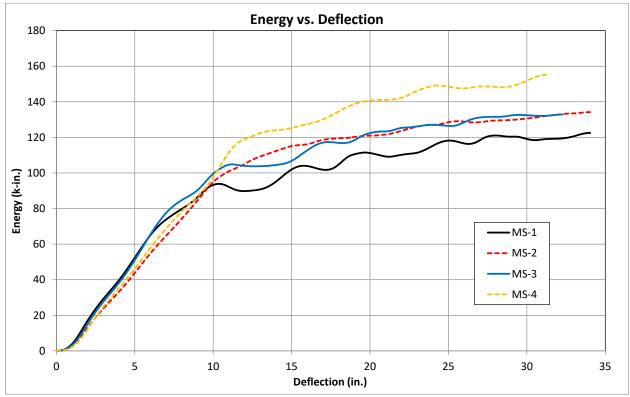

Figure 20. Energy vs. Deflection Comparison, Component Testing - Round 1

5 COMPONENT TESTING – ROUND 2, SOCKETED POSTS

5.1 Purpose

From the first round of dynamic component testing, it was determined that asphalt pavements were not strong enough to support driven S3x5.7 (S76x8.5) guardrail posts without sustaining damage during impact events. The impact load needed to be distributed over a larger area of the asphalt to prevent the post from translating and rotating through the asphalt. Therefore, Round 2 of dynamic component testing was conducted to evaluate the use of steel sockets or sleeves with and without shear plates within asphalt mow strips to prevent pavement damage.

5.2 Scope

Round 2 of component testing consisted of five tests conducted on S3x5.7 (S76x85) posts installed within 4-in. (102-mm) thick asphalt mow strips, as shown in Figures 21 through 24. In all five tests, steel sockets measuring 4 in. x 4 in. x ¹/₄ in. (102 mm x 102 mm x 6 mm) were utilized to house the guardrail posts and distribute the load. In test nos. MSSP-1 through MSSP-4, a steel shear plate was welded to the backside of the socket to further distribute the impact load. The test article in test no. MS-5 did not utilize a shear plate on the socket. The length, or embedment depth, of the socket varied throughout the testing matrix to evaluate the minimum depth required to prevent damage. All tests were conducted with an impact height of 12 in. (305 mm) and a targeted impact speed of 20 mph (32 km/h). Four of the tests were conducted with impact angles of 90 degrees causing strong-axis bending, while test no. MSSP-2 was conducted at a 0 degree impact angle to evaluate longitudinal impacts (weak-axis bending) to the post and socket assembly. The complete test matrix for Round 2 component testing is shown in Table 9.

The same 4-in. (102-mm) asphalt pad from the first round of component testing was utilized during Round 2 of component testing. The S3x5.7 (S76x8.5) posts were designated as

A36 steel. However, the posts were fabricated from 50-ksi (345-MPa) steel that also satisfied A992 requirements. This increased strength resulted in a more critical evaluation of the mow strips. The sockets were fabricated from A500 Grade B steel, and the plates were cut from A572 Grade 50 steel. Material specifications, mill certifications, and certificates of conformity for the installation materials are shown in Appendix A.

All of the sockets were installed by driving them into the asphalt mow strip. Initially, the sockets were just capped with a flat plate at the bottom. However, when this configuration was driven into the mow strip, it punched a hole larger than the socket into the asphalt. Subsequently, two steel plates were welded to the base of the socket to form a triangular wedge. Through an experimentation process, the wedge plates shown in Figure 23 were developed to prevent damage to the asphalt and provide a tight fit around the socket. This design allowed the socket to be driven into place with minimal damage to the asphalt and provided a tight fit between the asphalt and the socket. The asphalt damage corresponding to both a wedge-shaped base and a flat base are illustrated in Figure 25.

		Mow Strip		Socket	Post Length	~~	Impact	Impact

5.3 Results

5.3.1 Test No. MS-5

Test no. MS-5 was conducted on August 23, 2013 at approximately 11:30 a.m. The weather conditions, per the National Oceanic and Atmosphere Administration (station 14939/LNK), were reported and are shown in Table 10.

Table 10. Weather Conditions, Test No. MS-5

Temperature	86° F
1 1	
Humidity	57%
Wind Speed	13 mph
Wind Direction	170° From True North
Sky Conditions	Sunny
Visibility	10 Statute Miles
Pavement Surface	Dry
Previous 3-Day Precipitation	0.01 in.
Previous 7-Day Precipitation	0.01 in.

During test no. MS-5, the bogie impacted the S3x5.7 (S76x8.5) steel post at a speed of 21.7 mph (34.9 km/h) and an angle of 90 degrees, thus causing strong-axis bending in the post. At 0.004 sec after impact, the socket began displacing through the asphalt, and by 0.010 sec, a plastic hinge had formed in the post at the groundline. The post continued to bend backward until the bogie head overrode the top of the post 0.116 sec after impact.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 26. Upon impact, the resistance force increased rapidly to 13.6 kips (60.5 kN) at a displacement of 2.0 in. (51 mm). The force then peaked at 14.7 kips (65.4 kN) at a displacement of 5.7 in. (145 mm). At 0.030 sec and a displacement of 10 in. (254 mm), the bogie head was sliding up the post as it bent over, resulting in a force reduction. Subsequently, the resistance force oscillated until the bogie head overrode the post at a displacement of 35.5 in. (902 mm). At this deflection, 140 k-in. (15.8 kJ) of energy was dissipated.

Damage to the test article consisted of plastic bending of the post at the groundline, rotation of the steel socket, and displacement and spalling of the asphalt. The socket had rotated backward leaving a 1-in. (25-mm) gap between the asphalt and the front edge of the socket. Additionally, the asphalt on the back side of the socket displaced, which caused cracking and spalling. The post was easily removed from the socket without further damage to the asphalt. However, the asphalt displacement would require repairs, and the socket would need to be reset prior to replacing the damaged post. The backside of the socket sustained minor deformations from the post bearing against it, but the damage was minimal and the socket remained reusable. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 27 and 28, respectively.

47

5.3.2 Test No. MSSP-1

Test no. MSSP-1 was conducted on May 30, 2014 at approximately 3:00 p.m. The weather conditions, per the National Oceanic and Atmosphere Administration (station 14939/LNK), were reported and are shown in Table 11.

Temperature	85° F		
Humidity	48%		
Wind Speed	13 mph		
Wind Direction	140° From True North		
Sky Conditions	Cloudy		
Visibility	10 Statute Miles		
Pavement Surface	Dry		
Previous 3-Day Precipitation	0.00 in.		
Previous 7-Day Precipitation	1.34 in.		

Table 11. Weather Conditions, Test No. MSSP-1

During test no. MSSP-1, the bogie impacted the S3x5.7 (S76x8.5) steel post at a speed of 21.4 mph (34.4 km/h) and an angle of 90 degrees, thus causing strong-axis bending in the post. By 0.010 sec, a plastic hinge had formed in the post at the groundline. The post continued to bend backward until the bogie head overrode the top of the post 0.098 sec after impact.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 29. Upon impact, the resistance force increased rapidly and peaked at 16.5 kips (73.4 kN) at a displacement of 3.6 in. (91 mm). At 0.020 sec and a displacement of 7 in. (178 mm), the bogie head was sliding up the post as it bent over, resulting in the force dropping below 10 kips (4.5 kN). The resistance force oscillated below 5 kips (22.2 kN) until the bogie head overrode the post at a displacement of 31.4 in. (798 mm). At this deflection, 122.1 k-in. (13.8 kJ) of energy was dissipated.

Damage to the test article consisted of plastic bending of the post at the groundline, displacement of the steel socket through the asphalt, and minor bending of the steel shear plate. The socket rotated backward, leaving a ¹/₄-in. (6-mm) gap between the asphalt and the front edge of the socket. The free edges of the shear plate were bent forward slightly due to the socket displacement. The post was easily removed from the socket, and a new one could be installed plumb. Thus, no repairs were necessary on the asphalt or socket to replace the damaged post. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 30 and 31, respectively.

Visibility	10 Statute Miles		
Pavement Surface	Dry		
Previous 3-Day Precipitation	1.54 in.		
Previous 7-Day Precipitation	2.27 in.		

Table 12. Weather Conditions, Test No. MSSP-2

Since damage was minimal during test no. MSSP-1, the same socket was utilized for test no. MSSP-2 without removing or resetting the socket. During test no. MSSP-2, the bogie impacted the S3x5.7 (S76x8.5) steel post at a speed of 20.1 mph (32.3 km/h) and an angle of 0 degrees, thus causing weak-axis bending in the post. By 0.008 sec after impact, a plastic hinge had formed in the post at the groundline. The post continued to bend backward until the bogie head overrode the top of the post 0.104 sec after impact.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 32. Upon impact, the resistance force increased rapidly to a peak of 5.4 kips (24.0 kN) at a displacement of 1.8 in. (46 mm). Another force peak of 4.9 kips (21.8 kN) occurred at 10.1 in. (257 mm) before the bogie head began to slide up the post as it bent over. Subsequently, the resistance force oscillated below 3.5 kips (15.6 kN) until the bogie head

overrode the post at a displacement of 33.4 in. (848 mm). At this deflection, 80.6 k-in. (9.1 kJ) of energy was dissipated.

Damage to the test article consisted of plastic bending of the post at the groundline and minor displacement of the socket. The socket had rotated slightly, leaving a ¹/₈-in. (3-mm) gap between the asphalt and the upstream edge of the socket. The post was easily removed from the socket, and a new one could be installed plumb. Thus, no repairs were necessary on the asphalt or socket to replace the damaged post. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 33 and 34, respectively.

Previous 3-Day Precipitation	0.00 in.		
Previous 7-Day Precipitation	0.00 in.		

Table 13. Weather Conditions, Test No. MSSP-3

During test no. MSSP-3, the bogie impacted the S3x5.7 (S76x8.5) steel post at a speed of 20.5 mph (33.0 km/h) and an angle of 90 degrees, thus causing strong-axis bending in the post. At 0.006 seconds after impact, the socket began displacing through the asphalt, and by 0.018 seconds, shear cracks had formed between the socket and the backside of the asphalt. By 0.040 sec, the asphalt behind the socket had completely broken free from the mow strip and was displacing backward. The socket and post continued to rotate backward until the bogie head overrode the top of the post 0.156 sec after impact.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 35. Upon impact, the resistance force increased rapidly to 12.6 kips (56.0 kN) at a displacement of 1.8 in. (46 mm). The force then peaked at 20.0 kips (89.0 kN) at a displacement of 4.1 in. (104 mm). At a displacement of 12 in. (305 mm), the asphalt behind the socket had broken away. Subsequently, the resistance force dropped and oscillated below 5 kips

(22.2 kN) until the bogie head overrode the post at a displacement of 41.0 in. (1,041 mm). At this deflection, the 190.5 k-in. (21.5 kJ) of energy was dissipated.

Damage to the test article consisted largely of asphalt cracking, fracture, and displacement. The asphalt behind the socket and post assembly fractured from the mow strip due to three large shear cracks formed between the socket and the back edge of the asphalt strip. Additional asphalt cracks were found directly in front of the socket's original position. These cracks and fractures allowed the socket and post assembly to rotate backward during impact. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 36 and 37, respectively.

Table 14. Weather Conditions, Test No. MSSP-4

During test no. MSSP-4, the bogie impacted the S3x5.7 (S76x8.5) steel post at a speed of 20.8 mph (33.5 km/h) and an angle of 90 degrees, thus causing strong-axis bending in the post. At 0.008 sec after impact, the socket began displacing through the asphalt, and by 0.010 sec, a plastic hinge had formed in the post at the groundline. The post continued to bend backward until the bogie head overrode the top of the post 0.104 sec after impact.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 38. Upon impact, the resistance force increased rapidly to a peak force of 16.3 kips (72.5 kN) at a displacement of 3.5 in. (89 mm). By 0.030 sec and a displacement of 10 in. (254 mm), the bogie head was sliding up the post as it bent over, resulting in a force reduction. Subsequently, the resistance force oscillated below 3 kips (13.3 kN) until the bogie head overrode the post at a displacement of 31.2 in. (792 mm). At this deflection, 142.1 k-in. (16.1 kJ) of energy was dissipated.

Damage to the test article consisted of plastic bending of the post at the groundline, displacement of the steel socket, and slight bending of the shear plate. The socket had rotated backward, leaving a ¹/₂-in. (13-mm) gap between the asphalt and the front edge of the socket. Due to this movement, the free edges of the shear plate were bent slightly forward. The post was easily removed from the socket, and a new one could be installed plumb. Thus, no repairs were necessary for the asphalt or socket to replace the damaged post. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 39 and 40, respectively.

5.4 Discussion

The results from Round 2 of dynamic component testing are summarized in Table 15. The addition of the 4-in. (102-mm) square socket used in test no. MS-5 reduced the amount of asphalt displacement and damage sustained during the test. However, the 1 in. (25 mm) of socket displacement at the groundline was greater than desired and would prevent a replacement post from being installed plumb. The addition of the 10-in. x 9-in. x ¼-in. (254-mm x 229-mm x 6-mm) shear plate further reduced asphalt damage and limited the socket to displacements that would allow for post replacement without resetting the socket. Thus, the steel shear plate would be necessary for installations to prevent damage to asphalt mow strips during vehicle impacts into the barrier system.

Even with the addition of the shear plate, the depth of the socket proved to be a critical factor, as shown in test nos. MSSP-1, MSSP-3, and MSSP-4. In test no. MSSP-3, the socket with a 20-in. (508-mm) embedment depth was too weak, as it overloaded the asphalt and caused major cracking and fracture of the mow strip. Subsequently, the 20-in. (508-mm) long socket rotated through the soil and the S3x5.7 (S76x8.5) post did not yield. Alternatively, in test nos. MSSP-1 and MSSP-4, socket embedment depths of 30 in. (762 mm) and 24 in. (610 mm) resulted in socket displacements of ¼ in. (6 mm) and ½ in. (13 mm) respectively. Both of these socket displacements/rotations allowed for a replacement post to be installed plumb without repairs to the asphalt or resetting the socket. Note, displacements greater than ½ in. (13 mm) would likely require repair work prior to installing a new post.

One test was also conducted along the longitudinal axis, thus causing weak-axis bending of the post. Test no. MSSP-2 was conducted on a 30-in. (762-mm) long socket with the shear plate oriented parallel to the impact trajectory. Thus, the shear plate had minimal effect on the socket's resistance to displacement. The test resulted in a minimal socket displacement of ½ in. (3 mm). Due to the reduction in the bending strength of the S3x5.7 (S76x8.5) post in the weak axis as compared to the strong axis, longitudinal impacts did not appear to cause significant damage to the socket or asphalt mow strip, and similar results would be expected if a longitudinal test were conducted on a 24-in. (610-mm) long socket.

Force vs. displacement and energy vs. displacement comparisons for all five tests are shown in Figures 41 and 42, respectively. The resistance forces and absorbed energies for each test corresponded to the failure mechanism of that test. The three tests that resulted in strong-axis bending of the post, test nos. MS-1, MSSP-1, and MSSP-4, had similar peak loads, force curve shapes, and absorbed energies. Test no. MSSP-3 showed a much different load curve, as the asphalt around the socket fractured and allowed the socket to rotate during the impact event. This behavior prolonged the impact duration and resulted in increased energy absorption. As would be expected, test no. MSSP-2, which resulted in weak-axis bending of the post, showed a much lower resistive force.

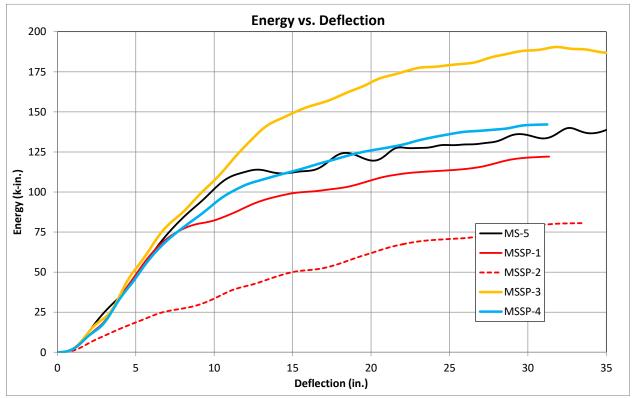

Figure 42. Energy vs. Deflection Comparison, Component Testing - Round 2

6 COMPONENT TESTING - ROUND 3, DUAL-POST TESTING

6.1 Purpose

The first two rounds of component testing were conducted on weak guardrail posts installed within mow strips to evaluate the damage associated with various pavement types and socket sizes. These tests revealed that a 4-in. (102-mm) thick concrete mow strip was strong enough to support an S3x5.7 (S76x8.5) post and prevent damage mow strip during impact events. The 4-in. (102-mm) thick asphalt mow strip required a steel tube socket with a minimum embedment depth of 24 in. (610 mm) and a backside shear plate to distribute impact loads and prevent damage to the pavement. All of these tests were conducted on single posts within the mow strip and actual barrier system installations will have multiple posts spaced at 37.5-in. (953-mm) intervals. Previous full-scale crash testing has shown that up to 11 posts may be loaded during a single vehicle impact event [7]. Therefore, it was deemed necessary to investigate damage to both mow strip pavements that would result from loading multiple posts simultaneously.

6.2 Scope

Round 3 of component testing consisted of two tests conducted on dual S3x5.7 (S76x85) posts installed 37.5 in. (953 mm) apart within mow strips, as shown in Figures 43 through 46. Test no. MSSP-5 was conducted within a 4-in. (102-mm) thick asphalt mow strip and utilized 24-in. (610-mm) long, 4-in. x 4-in. x ¹/₄-in. (102-mm x 102-mm x 6-mm) steel tube sockets to support the posts. Additionally, 9-in. x 10-in. x ¹/₄-in. (229-mm x 254-mm x 6-mm) shear plates were welded to the backside of the sockets to distribute the impact loads. Two plates were welded to the base of each socket to form a wedge, which allowed the socket to be driven into place without damaging the surrounding asphalt. Test no. MSSP-6 was conducted within a 4-in.

(102-mm) thick, unreinforced concrete mow strip. The dual posts were installed through 4-in. (102-mm) square leave-outs in the concrete and had an embedment depth of 40 in. (1,016 mm).

The dual-post tests under Round 3 of component testing were conducted with the same impact conditions utilized during the previous rounds of component testing. The bogie vehicle impacted the posts at a height of 12 in. (305 mm) and a target impact speed of 20 mph (32 km/h) and at an angle of 90 degrees, thus causing strong-axis bending. The complete test matrix for Round 3 of component testing is shown in Table 16.

The unreinforced concrete mow strip was constructed from a concrete mix with a compressive strength of 4,000 psi (28 MPa). The asphalt mow strip was constructed from a 52-34 grade binder typically utilized in highway shoulder construction in Nebraska. The S3x5.7 (S76x8.5) posts were designated as A36 steel. However, the posts were fabricated from 50-ksi (345-MPa) steel that also satisfied A992 requirements. This increased strength resulted in a more critical evaluation of the mow strips. The sockets were fabricated from A500 Grade B steel, and the plates were cut from A572 Grade 50 steel. Material specifications, mill certifications, and certificates of conformity for the installation materials are shown in Appendix A.

	Mow	v Strip		Post	-	Impact	Impact Angle deg.	
Test No.	Material	Thickness in. (mm)	Posts	Spacing in. (mm)	Post Installation	Speed mph (km/h)		
MSSP-5	Asphalt	4 (102)	Dual S3x5.7	37.5 (953)	24" Long Socket with Shear Plate	20 (32)	90°	
MSSP-6	Concrete	4 (102)	Dual S3x5.7	37.5 (953)	4"x4" Hole in Concrete	20 (32)	90°

6.3 Results

6.3.1 Test No. MSSP-5

Test no. MSSP-5 was conducted on August 25, 2014 at approximately 2:40 p.m. The weather conditions, per the National Oceanic and Atmosphere Administration (station 14939/LNK), were reported and are shown in Table 17.

	-					
Temperature	79° F					
Humidity	49%					
Wind Speed	17 mph

Visibility	10 Statute Miles					
Pavement Surface	Dry					
Previous 3-Day Precipitation	0.21in.					
Previous 7-Day Precipitation	0.62in.					

Table 17. Weather Conditions, Test No. MSSP-5

During test no. MSSP-5, the bogie impacted the dual S3x5.7 (S76x8.5) steel posts at a speed of 18.6 mph (29.9 km/h) and an angle of 90 degrees, thus causing strong-axis bending in the posts. At 0.010 sec after impact, the sockets began displacing through the asphalt, and the posts begun to bend and yield at the groundline. At 0.020 seconds, shear cracks began to form in the asphalt behind the sockets. By 0.042 sec, the asphalt behind the sockets had completely broken free from the rest of mow strip and was displacing backward. The sockets and posts continued to rotate backward until the bogie head overrode the posts 0.150 sec after impact.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 47. Upon impact, the resistance force increased rapidly to 17.3 kips (77.0 kN) at a displacement of 1.4 in. (36 mm). The force then peaked at 27.3 kips (121.4 kN) at a displacement of 3.8 in. (97 mm). By 0.042 sec and a displacement of 10 in. (254 mm), the

asphalt behind the sockets had broken away, which allowed the sockets and posts to rotate backward. Subsequently, the resistive force dropped steadily until the bogie head overrode the posts at a displacement of 19.5 in. (495 mm). At this deflection, 227.9 k-in. (25.7 kJ) of energy was dissipated.

Damage to the test article consisted of post bending, socket displacement, and asphalt cracking, fracture, and displacement. The asphalt behind the socket and post assemblies fractured away from the mow strip due to large shear cracks, which formed between the two sockets and also extended from the outside edges of the sockets to the back of the asphalt mow strip. These cracks were measured to be between 1.5 in. and 3 in. (38 mm and 76 mm) wide directly behind the sockets. An additional asphalt crack was found directly behind the left socket extending parallel to the direction of impact. These cracks and fractures allowed the socket and post assemblies to rotate backward during impact. The posts were bent at the groundline, though not to the degree shown in test no. MSSP-4 due to the rotation of the sockets. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 48 and 49, respectively.

6.3.1 Test No. MSSP-6

Test no. MSSP-6 was conducted on January 23, 2015 at approximately 11:30 a.m. The weather conditions, per the National Oceanic and Atmosphere Administration (station 14939/LNK), were reported and are shown in Table 18.

Temperature	40° F					
Humidity	55%					
Wind Speed	14 mph					
Wind Direction	200° From True North					
Sky Conditions	Sunny					
Visibility	10 Statute Miles					
Pavement Surface	Dry					
Previous 3-Day Precipitation	0.0 in.					
Previous 7-Day Precipitation	0.0 in.					

Table 18. Weather Conditions, Test No. MSSP-6

During test no. MSSP-6, the bogie impacted the dual S3x5.7 (S76x8.5) steel posts at a speed of 20.1 mph (32.3 km/h) and an angle of 90 degrees, thus causing strong-axis bending in the posts. By 0.010 sec after impact, the posts had begun to bend at the groundline, and at 0.016 sec, concrete spalling began directly behind the posts. The posts continued to bend backward until the bogie head overrode the top of the posts.

Force vs. deflection and energy vs. deflection curves were created from the accelerometer data and are shown in Figure 50. Upon impact, the resistance force increased rapidly and peaked at 28.3 kips (125.9 kN) at a displacement of 3.6 in. (91 mm). By 0.030 sec and a displacement of 8 in. (203 mm), the bogie head was sliding up the posts as they continued to bend. Subsequently, the resistance force steadily decreased until the bogie head overrode the posts at a displacement of 22.4 in. (569 mm). At this deflection, 249.3 k-in. (28.2 kJ) of energy was dissipated.

Damage to the test article consisted of plastic bending of the posts at the groundline and some surface spalling at the back edges of the concrete holes. However, the spalling was less than ¹/₄ in. (6 mm) deep, and cracking was not evident. The posts were removed without causing further damage. Thus, new posts could be installed without repairs to the concrete. Time-sequential photographs and pre- and post-impact photographs are shown in Figures 51 and 52, respectively.

6.4 Discussion

The results from Round 3 of dynamic component testing are summarized in Table 19. In test no. MSSP-5, the asphalt mow strip cracked and fractured due to the combined loading of the dual S3x5.7 (S76x8.5) posts installed in 24-in. (610-mm) deep sockets. Recall, the 24-in. (610-mm) socket was successfully tested in a single post configuration in test no. MSSP-4 of Round 2 component testing. However, the addition of a second post produced excessive shear loads and mow strip failure. The fracture shape of the asphalt behind the socket and post assemblies was consistent with a shear block failure pattern. Essentially, loading two posts close together doubled the shear loads as compared to a single post, while the shear area behind the posts was only minimally increased. Similar block shear failure of the asphalt would be expected for this configuration if utilized in an actual barrier system installation. Thus, a stronger mow strip would be required to prevent damage observed in actual barrier installations.

In test no. MSSP-6, the concrete mow strip withstood the impact loads imparted by the dual S3x5.7 (S76x8.5) posts without sustaining any significant damage. The spalling that occurred on the backside of the leave-out holes was only cosmetic damage and did not affect the strength of the concrete mow strip.

Force vs. displacement and energy vs. displacement comparisons for both tests are shown in Figures 53 and 54, respectively. The resistance force curves between the two tests were similar in shape. However, the magnitude of the force curve from test no. MSSP-6 was higher due to the asphalt pavement fracture in test no. MSSP-5, which allowed the socket to rotate backward. As a result, the absorbed energy for the concrete mow strip configuration was higher than that of the asphalt mow strip configuration.

Test No.	Mow Strip		Socket Emb.	Shear	Impact Velocity	Peak Force	Average Force kips (kN)		Total Energy	Mow Strip	
	Material	Thickness in. (mm)	Posts	Depth in. (mm)	Plate	mph (km/h)	kips (kN)	@10"	@15"	Absorbed k-in. (kJ)	Damage

7 BARRIER DESIGN DETAILS

Component testing results illustrated that asphalt mow strips were susceptible to damage and shear fracture even when utilizing a 24-in. (610-mm) long steel socket with a backside shear plate to support the S3x5.7 (S76x8.5) guardrail posts. However, the project sponsors desired to continue testing with an asphalt mow strip due to the frequent use of asphalt mow strips. Three options were identified to strengthen the mow strip and reduce the impact loads to the mow strip: (1) increase the thickness of the mow strip; (2) increase the width of the mow strip; and (3) increase the embedment depth of the socket. After reviewing these options, the project sponsors elected to utilize both options 1 and 3. Thus, the thickness of the mow strip was increased to 6 in. (152 mm), and the embedment depth of the sockets was increased to 30 in. (762 mm).

The weak-post guardrail test installation was 175 ft (53.3 m) long and consisted of Wbeam guardrail, a combination of strong and weak guardrail posts, an asphalt mow strip, and guardrail end anchorage systems, as shown in Figures 55 through 67. Photographs of the test installation are shown in Figures 68 and 69. Material specifications, mill certifications, and certificates of conformity for the system materials are shown in Appendix C.

The W-beam guardrail was mounted with a top-rail height of 31 in. (787 mm) throughout the entire system. The middle of the guardrail installation was constructed along the centerline of a 75-ft (22.9-m) long by 4-ft (1.2-m) wide by 6-in. (152-mm) thick asphalt mow strip. Within this region, the 12-ga (2.66-mm thick) W-beam guardrail was supported by 23 S3x5.7 (S76x8.5) weak posts spaced at 37.5 in. (953 mm) on center. The W-beam was connected to the weak posts utilizing $\frac{5}{16}$ -in. (8-mm) diameter bolts and 1³/₄-in. x 1³/₄-in. (44-mm x 44-mm) square washers.

As utilized in the original weak-post MGS bridge rail system, 6-in. (152-mm) long backup plates were intended to be utilized between each weak post and the W-beam rail. However, an error in the design drawings resulted in specifying the 12-in. (305-mm) long backup plates previously used in the non-blocked MGS system [12]. Thus, the test installation was assembled utilizing the 12-in. (305-mm) long backup plates at weak post locations. Unfortunately, the 12-in. (305-mm) long backup plates do not fit within the 8-in. (203-mm) space between the bolts at W-beam rail splices. Therefore, weak posts that coincided with W-beam rail splice locations did not have backup plates.

Each weak post was inserted into a 4-in. x 4-in. x ¹/₄-in. (102-mm x 102-mm x 6-mm) steel tube socket, which measured 30 in. (762 mm) long and had a 10-in. x 9-in. x ¹/₄-in. (254-mm x 229-mm x 6-mm) shear plate welded to its backside. Steel plates were welded to the bottom of each socket to form a wedge, so that the socket could be installed by driving it through the asphalt pavement, similar to the previous component test installations. However, the additional pavement thickness, in combination with cooler temperatures, caused the asphalt pad to crack during the installation of the first two posts. Therefore, 3-in. (76-mm) diameter holes were cored in the asphalt prior to driving the remaining sockets to prevent any further damage during the installation of the system.

Standard MGS guardrail was placed directly upstream and downstream of the simulated asphalt mow strip. The MGS utilized W6x8.5 (W152x12.6) strong posts spaced at 75 in. (1,905 mm) on center. Standard 12-in. (305-mm) deep timber blockouts were utilized in the connection between the guardrail and the strong posts in these regions of the system. The ends of the installation consisted of guardrail trailing-end anchorage systems, as shown in Figures 57 through 62. This guardrail anchor was developed to simulate the strength of other crashworthy end terminals and was successfully crash tested to MASH TL-3 standards as a trailing-end anchor [13].

8 TEST REQUIREMENTS AND EVALUATION CRITERIA

8.1 Test Requirements

Longitudinal barriers, such as W-beam guardrails, must satisfy impact safety standards in order to be declared eligible for federal reimbursement by the Federal Highway Administration (FHWA) for use on the National Highway System (NHS). For new hardware, these safety standards consist of the guidelines and procedures published in MASH [9]. According to TL-3 of MASH, longitudinal barrier systems must be subjected to two full-scale vehicle crash tests, as summarized in Table 20.

	Test		Vehicle	Impact C	onditions	
Test Article	Designation No.	Test Vehicle	Weight, lb (kg)	Speed, mph (km/h)	Angle, deg.	Evaluation Criteria ¹
Longitudinal	3-10	1100C	2,425 (1,100)	62 (100)	25	A,D,F,H,I
Barrier	3-11	2270P	5,000 (2,270)	62 (100)	25	A,D,F,H,I

Table 20. MASH TL-3 Crash Test Conditions for Longitudinal Barriers

¹ Evaluation criteria explained in Table 21.

Prior research has shown successful safety performance for small cars impacting the original weak-post MGS bridge rail system from which this guardrail system was adapted [7-8]. The MASH 3-10 small car test conducted on the MGS bridge rail system did not show potential for any occupant risk problems arising from vehicle pocketing, wheel snagging on the guardrail posts, occupant compartment penetration, potential for rail rupture, or vehicular instabilities due to vaulting or climbing the rail. Additionally, the MASH 3-11 pickup truck test imparted significantly greater impact loads and higher displacements to the system compared to the 1100C test. Since the current project sought to develop proper attachment of the weak-post system to

prevent damage to mow strips, the 2270P test was identified as the critical test in the system evaluation. Therefore, the 1100C small car test, MASH test designation no. 3-10, was deemed unnecessary for evaluation of the weak-post guardrail system in mow strips.

8.2 Evaluation Criteria

Evaluation criteria for full-scale vehicle crash testing are based on three appraisal areas: (1) structural adequacy, (2) occupant risk, and (3) vehicle trajectory after collision. Criteria for structural adequacy are intended to evaluate the ability of the guardrail system to contain and redirect impacting vehicles. In addition, controlled lateral deflection of the test article is acceptable. Occupant risk evaluates the degree of hazard to occupants in the impacting vehicle. Post-impact vehicle trajectory is a measure of the potential of the vehicle to result in a secondary collision with other vehicles and/or fixed objects, thereby increasing the risk of injury to the occupants of the impacting vehicle and/or other vehicles. These evaluation criteria are summarized in Table 21 and are defined in greater detail in MASH. The full-scale vehicle crash test was conducted and reported in accordance with the procedures provided in MASH.

In addition to the standard occupant risk measures, the Post-Impact Head Deceleration (PHD), the Theoretical Head Impact Velocity (THIV), and the Acceleration Severity Index (ASI) were determined and reported on the test summary sheet. Additional discussion on PHD, THIV, and ASI is provided in MASH.

8.3 Soil Strength Requirements

In accordance with Chapter 3 and Appendix B of MASH, foundation soil strength must be verified before any full-scale crash testing can occur. During the installation of a soildependent system, additional W6x16 (W152x23.8) posts are to be installed near the impact region utilizing the same installation procedures as the system itself. Prior to full-scale crash testing, a dynamic impact test must be conducted to verify a minimum dynamic soil resistance of 7.5 kips (33.4 kN) at post deflections between 5 and 20 in. (127 and 508 mm) measured at a height of 25 in. (635 mm). If dynamic testing near the system is not desired, MASH permits a static test to be conducted instead and compared against the results of a previously-established baseline test. In this situation, the soil must provide a resistance of at least 90 percent of the static baseline test at deflections of 5, 10, and 15 in. (127, 254, and 381 mm). Further details can be found in Appendix B of MASH.

Table 21. MASH Evaluation Criteria for Longitudinal Barriers

Structural Adequacy	A.	Test article should contain a vehicle to a controlled stop underride, or override the in deflection of the test article is	p; the vehicle shound shou shou shou shou shou shou shou shou	ild not penetrate,			
	D.	should not penetrate or show compartment, or present a pedestrians, or personnel in intrusions into, the occupant	etached elements, fragments or other debris from the test article nould not penetrate or show potential for penetrating the occupant ompartment, or present an undue hazard to other traffic, edestrians, or personnel in a work zone. Deformations of, or atrusions into, the occupant compartment should not exceed limits et forth in Section 5.3 and Appendix E of MASH.				
	F.	The vehicle should remain upright during and after collision. The maximum roll and pitch angles are not to exceed 75 degrees.					
Occupant	H.	Occupant Impact Velocity (OIV) (see Appendix A, Section A5.3 of MASH for calculation procedure) should satisfy the following limits:					
Risk		Occupant Impact Velocity Limits					
		Component	Preferred	Maximum			
		Longitudinal and Lateral	30 ft/s (9.1 m/s)	40 ft/s (12.2 m/s)			
	I.	The Occupant Ridedown Acceleration (ORA) (see Appendix A, Section A5.3 of MASH for calculation procedure) should satisfy the following limits:					
		Occupant Ridedown Acceleration Limits					
		Component	Preferred	Maximum			
		Longitudinal and Lateral	15.0 g's	20.49 g's			

9 TEST CONDITIONS

9.1 Test Facility

The testing facility was located at the Lincoln Air Park on the northwest side of the Lincoln Municipal Airport and is approximately 5 miles (8.0 km) northwest of the University of Nebraska-Lincoln city campus.

9.2 Vehicle Tow and Guidance System

A reverse cable tow system with a 1:2 mechanical advantage was used to propel the test vehicle. The distance traveled and the speed of the tow vehicle were one-half those of the test vehicle. The test vehicle was released from the tow cable before impact with the barrier system. A digital speedometer on the tow vehicle increased the accuracy of the test vehicle impact speed.

A vehicle guidance system developed by Hinch [14] was used to steer the test vehicle. A guide flag, attached to the left-front wheel and the guide cable, was sheared off before impact with the barrier system. The ³/₈-in. (9.5-mm) diameter guide cable was tensioned to approximately 3,500 lb (15.6 kN) and supported both laterally and vertically every 100 ft (30.5 m) by hinged stanchions. The hinged stanchions stood upright while holding up the guide cable, but as the vehicle was towed down the line, the guide flag struck and knocked each stanchion to the ground.

9.3 Test Vehicles

For test no. MGSMS-1, a 2007 Dodge Ram 1500 was used as the test vehicle. The curb, test inertial, and gross static vehicle weights were 5,225 lb (2,371 kg), 5,016 lb (2,275 kg), and 5,182 lb (2,351 kg), respectively. The test vehicle is shown in Figure 70, and vehicle dimensions are shown in Figure 71.

Figure 71. Vehicle Dimensions, Test No. MGSMS-1

The longitudinal component of the center of gravity (c.g.) was determined using the measured axle weights. The Suspension Method [15] was used to determine the vertical component of the c.g. for the pickup truck. This method is based on the principle that the c.g. of any freely suspended body is in the vertical plane through the point of suspension. The vehicle was suspended successively in three positions, and the respective planes containing the c.g. were established. The intersection of these planes pinpointed the final c.g. location for the test inertial condition. The location of the final c.g. is shown in Figures 71 and 72. Data used to calculate the location of the c.g. and ballast information are shown in Appendix D.

Square, black- and white-checkered targets were placed on the vehicle for reference to be viewed from the high-speed digital video cameras and aid in the video analysis, as shown in Figure 72. Round, checkered targets were placed on the center of gravity on the left-side door, the right-side door, and the roof of the vehicle.

The front wheels of the test vehicle were aligned to vehicle standards, except the toe-in value was adjusted to zero so that the vehicles would track properly along the guide cable. A 5B flash bulb was mounted on the left side of the vehicle's dash and was fired by a pressure tape switch mounted at the impact corner of the bumper. The flash bulb was fired upon initial impact with the test article to create a visual indicator of the precise time of impact on the high-speed videos. A remote-controlled brake system was installed in the test vehicle so the vehicle could be brought safely to a stop after the test.

9.4 Simulated Occupant

For test no MGSMS-1, a Hybrid II 50th-Percentile, Adult Male Dummy, equipped with clothing and footwear, was placed in the right-front seat of the test vehicle with the seat belt fastened. The dummy, which had a final weight of 166 lb (75 kg), was represented by model no.

572, serial no. 451, and was manufactured by Android Systems of Carson, California. As recommended by MASH, the dummy was not included in calculating the c.g location.

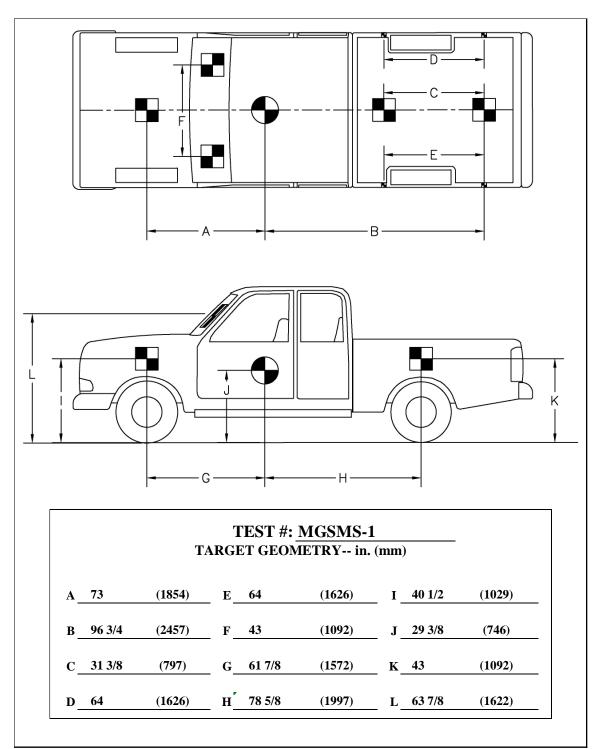

Figure 72. Target Geometry, Test No. MGSMS-1

9.5 Data Acquisition Systems

9.5.1 Accelerometers

Two environmental shock and vibration sensor/recorder systems were used to measure the accelerations in the longitudinal, lateral, and vertical directions. All of the accelerometers were mounted near the center of gravity of the test vehicle. The electronic accelerometer data obtained in dynamic testing was filtered using the SAE Class 60 and the SAE Class 180 Butterworth filters conforming to SAE J211/1 specifications [10].

The primary accelerometer system, the DTS unit, was a two-arm piezoresistive accelerometer system manufactured by Endevco. Three accelerometers were used to measure each of the longitudinal, lateral, and vertical accelerations independently at a sample rate of 10,000 Hz. The accelerometers were configured and controlled using a system developed and manufactured by Diversified Technical Systems, Inc. (DTS) of Seal Beach, California. More specifically, data was collected using a DTS Sensor Input Module (SIM), Model TDAS3-SIM-16M. The SIM was configured with 16 MB SRAM and eight sensor input channels with 250 kB SRAM/channel. The SIM was mounted on a TDAS3-R4 module rack. The module rack was configured with isolated power/event/communications, 10BaseT Ethernet and RS232 communication, and an internal backup battery. Both the SIM and module rack were crashworthy. The "DTS TDAS Control" computer software program and a customized Microsoft Excel worksheet were used to analyze and plot the accelerometer data.

The secondary accelerometer system, the SLICE-2 unit, was a modular data acquisition system manufactured by DTS. The acceleration sensors were mounted inside the body of a custom-built SLICE 6DX event data recorder and recorded data at 10,000 Hz to the onboard microprocessor. The SLICE 6DX was configured with 7 GB of non-volatile flash memory, a range of ± 500 g's, a sample rate of 10,000 Hz, and a 1,650 Hz (CFC 1000) anti-aliasing filter.

The "SLICEWare" computer software program and a customized Microsoft Excel worksheet were used to analyze and plot the accelerometer data.

9.5.2 Rate Transducers

The primary angle rate sensor, the ARS-1500, with a range of 1,500 degrees/sec in each of the three directions (roll, pitch, and yaw) was used to measure the rates of rotation of the test vehicles. The angular-rate sensor was mounted on an aluminum block inside the test vehicle near the center of gravity and recorded data at 10,000 Hz to the DTS SIM. The raw data measurements were then downloaded, converted to the proper Euler angles for analysis, and plotted. The "DTS TDAS Control" computer software program and a customized Microsoft Excel worksheet were used to analyze and plot the angular rate sensor data.

A secondary angle rate sensor system used to measure the rates of rotation of the test vehicle was mounted inside the body of the SLICE-2. Each SLICE MICRO Triax ARS had a range of 1,500 degrees/sec in each of the three directions (roll, pitch, and yaw) and recorded data at 10,000 Hz to the onboard microprocessor. The raw data measurements were then downloaded, converted to the proper Euler angles for analysis, and plotted. The "SLICEWare" computer software program and a customized Microsoft Excel worksheet were used to analyze and plot the angular rate sensor data.

9.5.3 Retroreflective Optic Speed Trap

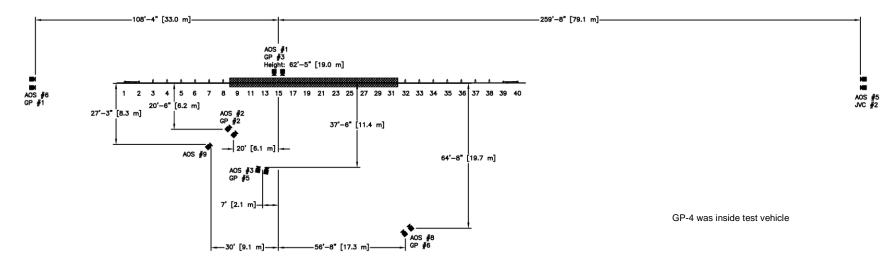

The retroreflective optic speed trap was used to determine the speed of the test vehicle before impact. Five retroreflective targets, spaced at approximately 18-in. (457-mm) intervals, were applied to the side of the vehicle. When the emitted beam of light was reflected by the targets and returned to the Emitter/Receiver, a signal was sent to the data acquisition computer, recording at 10,000 Hz, as well as the external LED box activating the LED flashes. The speed was then calculated using the spacing between the retroreflective targets and the time between

the signals. LED lights and high-speed digital video analysis are only used as a backup in the event that vehicle speeds cannot be determined from the electronic data.

9.5.4 Digital Photography

Seven AOS high-speed digital video cameras, six GoPro digital video cameras, and one JVC digital video camera were utilized to film test no. MGSMS-1. Camera details, camera operating speeds, lens information, and a schematic of the camera locations relative to the system are shown in Figure 73.

The high-speed videos were analyzed using ImageExpress MotionPlus and RedLake MotionScope software programs. Actual camera speed and camera divergence factors were considered in the analysis of the high-speed videos. A Nikon D50 digital still camera was used to document pre- and post-test conditions.

113

10 FULL-SCALE CRASH TEST NO. MGSMS-1

10.1 Static Soil Test

Before full-scale crash test no. MGSMS-1 was conducted, the strength of the foundation soil was evaluated with a static test, as described in MASH. The static test results, as shown in Appendix E, demonstrated a soil resistance above the baseline test limits. Thus, the soil provided adequate strength, and full-scale crash testing could be conducted on the barrier system.

10.2 Test No. MGSMS-1

The 5,182-lb (2,351-kg) pickup truck impacted the weak-post guardrail system at a speed of 63.0 mph (101.4 km/h) and an angle of 25.2 degrees. A summary of the test results and sequential photographs are shown in Figure 74. Additional sequential photographs are shown in Figures 75 through 78. Documentary photographs of the crash test are shown in Figure 79.

10.3 Weather Conditions

Test no. MGSMS-1 was conducted on December 5, 2014 at approximately 2:00 p.m. The weather conditions, as per the National Oceanic and Atmospheric Administration (station 14939/LNK), were reported and are shown in Table 22.

Temperature	52° F
Humidity	61%
Wind Speed	3 mph
Wind Direction	30° from True North
Sky Conditions	Sunny
Visibility	5.0 Statute Miles
Pavement Surface	Dry
Previous 3-Day Precipitation	0.0 in.
Previous 7-Day Precipitation	0.0 in.

Table 22. Weather Conditions, Test No. MGSMS-1

10.4 Test Description

Initial vehicle impact was to occur 16 ft (4.9 m) upstream from the rail splice at post no. 20, as shown in Figure 80, which was selected using the CIP plots found in Section 2.3 of MASH to maximize loading at a splice and the probability of wheel snag. The actual point of impact was 1 in. (25 mm) downstream from the targeted impact point. A sequential description of the impact events is contained in Table 23. The vehicle came to rest 119.8 ft (36.5 m) downstream from the point of impact and 3.8 ft (1.2 m) in front of the system. The vehicle trajectory and final position are shown in Figures 74 and 81.

TIME	EVENT				
(sec)					
0.000	The vehicle impacted the barrier $3\frac{1}{2}$ in. upstream from post no. 15.				
0.004	Post no. 15 began to deflect backward, and the right side of the bumper began to deform.				
0.008	Post nos. 14 and 16 began to deflect backward, and the right-front fender contacted the rail.				
0.012	Post nos. 13 and 17 began to deflect backward, and the right headlight deformed.				
0.016	Post nos. 18 – 21 deflected backward.				
0.018	The rail began to flatten between post nos. 15 and 16.				
0.024	Post no. 22 began to deflect backward.				
0.030	Post no. 23 began to deflect backward.				
0.038	Vehicle hood began to deform.				
0.042	Right-front tire contacted post no. 16, causing the rail to release from post no. 16.				
0.050	Asphalt cracks formed around post no. 16, and the asphalt began to shift backward.				
0.056	The rail released from post nos. 15 and 17.				
0.058	The vehicle began to yaw away from the system.				
0.064	The rail released from post no. 18.				
0.070	Right-front tire overrode post no. 16, and the vehicle began to roll toward the system.				
0.074	Right-front tire contacted post no. 17, and asphalt cracks were visible between post nos. 15 and 19.				
0.084	The right headlight became detached.				

Table 23. Sequential Description of Impact Events, Test No. MGSMS-1

0.100	Right-front tire contacted post no. 18, and the rail released from post no. 19.
0.122	Right-front tire contacted post no. 19.
0.128	The rail released from post no. 20, and the right-front tire deflated.
0.136	Soil heaves were visible behind the system as the asphalt shifted backward.
0.142	Asphalt cracking was visible between post nos. 14 and 22.
0.164	Front bumper contacted post no. 20.
0.172	The rail released from post no. 21.
0.180	Right-rear tire contacted post no. 16.
0.192	The right-rear quarter panel contacted the rail between post nos. 15 and 16.
0.196	The rail released form post no. 22.
0.244	Right-rear tire contacted post no. 17.
0.252	Right-front tire contacted post no. 21.
0.278	The vehicle was parallel to the system.
0.286	Right-front tire contacted post no. 22.
0.290	Right-front tire became airborne.
0.298	The rail released from post no. 23.
0.328	The right-front tire contacted post no. 23, and the right-rear tire contacted post no. 19.
0.340	The vehicle reached its maximum lateral deflection into the barrier.
0.368	Vehicle began to roll away from the system.
0.376	Right-front tire contacted post no. 24, causing the rail to release.
0.390	The vehicle began to yaw back toward the system.
0.422	Left-front tire regained contact with the ground.
0.668	The vehicle exited the system at a speed of 34 mph and at angle of 9.7 degrees.
0.786	The vehicle was again parallel with the system.
1.070	Left-front tire deflated.
1.742	A secondary impact occurred as the right-front fender contacted the rail upstream from post no. 39.

10.5 Barrier Damage

Damage to the barrier was moderate, as shown in Figures 82 through 88. Barrier damage consisted of guardrail bending and tearing, post bending, asphalt cracking and displacement, socket displacement, and contact marks on the guardrail and posts. The length of vehicle contact along the barrier was approximately 37 ft (11.3 m), which spanned from 4 in. (102 mm)

upstream from post no. 15 to 10 in. (254 mm) upstream from post no. 27. A secondary impact resulted in only minor deformations to the rail and posts and had a contact length of 8 ft (2.4 m), spanning from 16 in. (406 mm) downstream from post no. 37 to the splice between post nos. 38 and 39.

The W-beam guardrail displaced backward and had various bends, kinks, and scrapes between post nos. 13 and 29. The bottom of the guardrail was flattened between post nos. 15 and 22 and had a 10-in. (254-mm) long vertical tear in the downstream guardrail segment at the splice at post no. 20. The tear began at the bottom of the rail, extended vertically through the slot for the bottom downstream splice bolt, and continued upward and downstream until it terminated in the middle of the rail, as shown in Figure 88. All splice locations were measured before and after the test. The maximum splice movement of % in. (16 mm) was recorded at two adjacent splices in the contact region, which were located at post nos. 16 and 20. The rail and backup plates disengaged from post nos. 11 and 15 through 27. The detached backup plates were scattered behind the guardrail system. Only two of the plates traveled further than 15 ft (4.6 m) from the system, with the furthest found 25 ft (7.6 m) behind the guardrail system.

Nearly all of the posts outside of the contacted area were twisted and/or bent toward impact region. The upstream anchor post had a ¹/₄-in. (6-mm) soil gap on the upstream side of the post. Post nos. 13 through 15 and 27 were bent backward slightly, due to the lateral force on the rail. Post nos. 16 through 26 were all severely bent and twisted from direct vehicle contact during the impact event. Tears were found in various flanges of post nos. 16 through 21 due to bending and contact with the top of the sockets.

The asphalt mow strip was cracked and fractured down its centerline between post nos. 11 and 30, over a total length of 60 ft (18.3 m). The cracking was indicative of a shear block failure in the asphalt as it ran along the backside shear plates of each socket. The crack had a maximum opening width of $2\frac{1}{2}$ in. (64 mm) between post nos. 22 and 23 and steadily decreased to hairline cracks at its ends. The asphalt behind the fracture shifted laterally and caused the soil to heave behind the asphalt between post nos. 16 through 26. Additionally, the asphalt cracking allowed the sockets to translate and rotate backward. The maximum lateral displacement of the sockets was measured to be $1\frac{1}{2}$ in. (38 mm) at multiple post locations in the impact region.

The maximum permanent set of the rail and posts for the barrier system was 16¹/₂ in. (419 mm) located at the midspan between post nos. 17 and 18 and 29 in. (737 mm) at post no. 19, as measured in the field. The maximum lateral dynamic deflections of the rail and posts were 42.3 in. (1,074 mm) at post no. 18 and 34.2 in. (869 mm) at post no. 19, as determined from high-speed digital video analysis. The working width of the system was found to be 47.3 in. (1,201 mm), also determined from high-speed digital video analysis. Post no. 1, part of the upstream anchor, had displaced ¹/₄ in. (6 mm) downstream. The downstream BCT anchor posts did not displace.

10.6 Vehicle Damage

The damage to the vehicle was moderate, as shown in Figures 89 and 90. The maximum occupant compartment deformations are listed in Table 24 along with the deformation limits established in MASH for various areas of the occupant compartment. Note that none of the MASH-established deformation limits were violated. Complete occupant compartment and vehicle deformations and the corresponding locations are provided in Appendix F.

The majority of the damage was concentrated on the right-front corner of the vehicle where the impact occurred. The right-front bumper and fender were crushed inward, and the right headlight was disengaged. The plastic around the bumper was cracked and partially disengaged, and there was a kink in the bumper 13 in. (330 mm) from center. A 10-in. (254-mm) long tear in the fender was found behind the right headlight, and the front portion of the right fender was disengaged. A large dent was found above the wheel well spanning the length of the fender. The right side of the vehicle had various scrapes and gouges along its length. An 8-in. (203-mm) dent was located under the right taillight, while the taillight itself was partially disengaged. A kink was found in the rear bumper 21 in. (533 mm) from center.

The right-front tire was disengaged and deflated. A 3¹/₂-in. (89-mm) long tear was found on the tire sidewall, and the rim was cracked and gouged. The right-front brake caliper was disengaged and brake fluid was leaking. The steering knuckle was broken, and the wheel hub was fractured. The left-front tire was also deflated and the tire's rim was scraped. The roof and window glass remained undamaged.

10.7 Occupant Risk

The calculated occupant impact velocities (OIVs) and maximum 0.010-sec occupant ridedown accelerations (ORAs) in both the longitudinal and lateral directions are shown in Table 25. Note that the OIVs and ORAs were within the suggested limits provided in MASH. The calculated THIV, PHD, and ASI values are also shown in Table 25. The results of the occupant risk analysis, as determined from the accelerometer data, are summarized in Figure 74. The

recorded data from the accelerometers and the rate transducers are shown graphically in Appendix G.

10.8 Discussion

The analysis of the test results for test no. MGSMS-1 showed that the weak-post guardrail system in an asphalt mow strip adequately contained and redirected the 2270P vehicle with controlled lateral displacements of the barrier. There were no detached elements or fragments which showed potential for penetrating the occupant compartment or presented undue hazard to other traffic. Deformations of, or intrusions into, the occupant compartment that could have caused serious injury did not occur. The test vehicle did not penetrate or ride over the barrier and remained upright during and after the collision. Vehicle roll, pitch, and yaw angular displacements, as shown in Appendix G, were deemed acceptable because they did not adversely influence occupant risk safety criteria or cause rollover. After impact, the vehicle exited the barrier at an angle of 9.7 degrees, and its trajectory did not violate the bounds of the exit box. Therefore, test no. MGSMS-1, conducted on the weak-post guardrail system in an asphalt mow strip, was determined to be acceptable according to the MASH safety performance criteria for test designation no. 3-11.

11 SUMMARY, CONCLUSIONS, AND RECOMMENDATIONS

The objective of this project was to adapt the weak-post, MGS bridge rail system for use within asphalt mow strips. The new W-beam guardrail system was to withstand the impact force and dissipate energy through post bending, thereby limiting damage to the mow strip. It was desired that damaged barrier components could be replaced without requiring repairs to the mow strip in order to minimize maintenance costs.

The project began with a review of mow strip standards and practices from the Midwest States Pooled Fund Program members. Both asphalt and concrete mow strips were commonly used, and thicknesses varied between 3 in. (76 mm) and 6 in. (152 mm). However, a 4 ft (1.2 m) width was nearly unanimous for a standard mow strip. As such, the weak-post guardrail system was evaluated for use within 4-ft (1.2-mm) wide paved mow strips using either asphalt or concrete materials.

Dynamic bogie testing was conducted on weak posts installed in pavements to quantify the amount of damage expected within various mow strip configurations. Round 1 component testing consisted of four bogie impact tests on single S3x5.7 (S76x8.5) guardrail posts installed directly within the pavement. The posts were driven through the asphalt mow strips, while 4-in. (102-mm) square leave-outs and 4-in. (102-mm) diameter cored holes in the concrete allowed the posts to be driven through the concrete and into the underlying soil. Results from the Round 1 testing showed that the weak posts bent over and formed plastic hinges near the groundline. The 4-in. (102-mm) thick concrete mow strips suffered only minor spalling on the backside of the hole and leave-out. However, both the 4-in. (102-mm) and 6-in. (152-mm) thick asphalt mow strips spalled, cracked, and displaced, allowing the post to shift over 2 in. (51 mm) backward, as measured at the groundline. Removal of the damaged posts caused additional cracking in the asphalt pavements. Thus, distribution of the impact loads was required to prevent damage and repair concerns within asphalt mow strips.

Round 2 component testing consisted of five bogic impact tests on S3x5.7 (S76x8.5) posts installed within 4-in. x 4-in. x ¼-in. (102-mm x 102-mm x 6-mm) steel tube sockets, which were driven into the center of a 4-in. (102-mm) thick asphalt mow strip. The sockets had varied embedment depths ranging between 20 in. (508 mm) and 30 in. (762 mm). The first test on a 30-in. (762-mm) long socket resulted in the socket displacing 1 in. (25 mm) through the asphalt. Subsequently, 10-in. x 9-in. x ¼-in. (254-mm x 229-mm x 6-mm) shear plates were added to the backside of the sockets for the remainder of the component tests. With the addition of the shear plate, sockets measuring 30 in. (762 mm) and 24 in. (610 mm) resulted in displacements of ¼ in. (6 mm) and ½ in. (13 mm), respectively. Both of these displacements allowed a replacement post to be installed plumb without repair work to the asphalt or the socket. Testing on a 20-in. (508-mm) long socket resulted in asphalt shear fracture behind the socket and large displacements for the asphalt and the socket. Additionally, a single longitudinal impact test was conducted along the weak axis of the post installed in a 30-in. (762-mm) deep socket. The reduced strength of the post in the weak axis produced only ¼ in. (3 mm) of socket displacement.

Round 3 of dynamic component testing consisted of two tests on dual S3x5.7 (S76x8.5) weak posts spaced 37.5 in. (953 mm) apart to evaluate the ability of the mow strip pavement to withstand impact loading from multiple adjacent posts. Test no. MSSP-5 was conducted with dual posts installed in 24-in. (610-mm) deep sockets with backside shear plates driven into a 4-in. (102-mm) thick asphalt mow strip. During the test, the asphalt behind the sockets fractured and displaced backward. The crack pattern resembled a shear block failure, as the fracture extended between the two socket shear plates and then to the back edge of the mow strip at approximately 45 degree angles. Test no. MSSP-6 was conducted with dual posts installed

within 4-in. (102-mm) square leave-outs placed in a 4-in. (102-mm) thick unreinforced concrete mow strip. Similar to the previous single-post testing, the concrete sustained only minor spalling on the back edges of the leave-outs and would not require repair during replacement of the damaged posts.

Due to the widespread use of asphalt pavements as mow strips, the project sponsors desired to continue utilizing an asphalt mow strip during full-scale crash testing of the system. In an attempt to minimize the damage to the mow strip, the embedment depth of the socket was increased to 30 in. (762 mm), and the thickness of the mow strip was increased to 6 in. (152 mm). The full-scale test installation was 175 ft (53.3 m) long, though only the middle 75 ft (22.9 m) of the guardrail was installed over a simulated asphalt mow strip. The sockets and S3x5.7 (S76x8.5) weak posts were installed down the center of the mow strip at 37½-in. (953-mm) spacing. Soil fill was utilized in front of and behind the mow strip to create an even groundline around the barrier system. Standard MGS was installed upstream and downstream from the mow strip.

Test no. MGSMS-1 was conducted on the 31-in. (787-mm) tall weak-post guardrail installation in accordance with MASH test designation no. 3-11. During the test, the 2270P was contained and smoothly redirected. The barrier system had a maximum dynamic deflection of 42.3 in. (1,074 mm) and a working width of 47.3 in. (1,201 mm). Test no. MGSMS-1 satisfied all of the safety performance evaluation criteria for MASH TL-3 longitudinal barriers, as summarized in Table 26.

Unfortunately, the full-scale test also resulted in a large, 60-ft (18.3-m) long crack forming down the center of the asphalt mow strip throughout the impact region. The crack extended along the back side of the sockets, had a maximum opening width of 2¹/₂ in. (64 mm), and allowed the sockets to rotate and displace backward up to 1¹/₂ in. (38 mm). Consequently,

repairs to the asphalt and resetting of the sockets would be necessary when replacing damaged posts and rail segments. As such, the system did not to meet the design goal of limiting damage to the mow strip and preventing costly repairs. However, since the full-scale test satisfied the MASH TL-3 criteria, a couple options are recommended for installing this weak-post guardrail system within mow strips.

First, if asphalt damage during impact events was allowable, the system could be installed as tested. Of course, repairs to the mow strip would be expected when repairing impacted sections of the weak-post guardrail system, but the system would perform in a crashworthy manner. Mow strip repairs may include resetting of displaced sockets, filling of cracks and gaps around the socket, and/or the removal and replacement of damaged asphalt sections. During initial installation, the asphalt should be placed and compacted with standard rolling techniques for highway pavements, and the socket assemblies should be driven through the paved asphalt. Although the full-scale test utilized a 6-in. (152-mm) thick asphalt mow strip, a 4-in. (102-mm) thick asphalt mow strip should result in the same safety performance for the system. The thicker pavement was only selected in an attempt to prevent asphalt damage, an objective that was not achieved. Once the asphalt cracked along its center, the mow strip provided minimal resistance to prevent the socket from rotating backward. As such, the as-tested, weak-post guardrail system should perform adequately when installed down the center of an asphalt mow strip with a minimum width of 4 ft (1.2 m) and a minimum thickness of 4 in. (102 mm).

Second, if mow strip damage from impact events was not desirable, the weak-post guardrail system should be utilized within a concrete mow strip. Dynamic bogie testing on dual posts illustrated that 4-in. (102-mm) thick concrete mow strips do not carry the risk of block shear fracture associated with asphalt pavements. Thus, damage in the form of concrete cracking

and/or fracture would not be expected for concrete pavements. Additionally, dynamic bogie testing has shown that there is no need for a post socket within a concrete mow strip. The concrete mow strip was strong enough to contain the post and cause plastic bending at groundline. The concrete mow strip should have a minimum thickness of 4 in. (102 mm), a minimum width of 4 ft (1.2 m), and a minimum strength of 4,000 psi (28 MPa). Although not initially required for strength, reinforcement of the mow strip is recommended to prevent cracking and deterioration resulting from temperature shrinkage, freeze-thaw cycles, and/or settlement of the soil. Either 4-in. (102-mm) square leave-outs or 4-in. (102-mm) diameter cored holes should be placed along the center of the mow strip to allow for driving of the S3x5.7 (S76x8.5) posts. The posts should have a length of 6 ft (1.8 m) and an embedment depth of 40 in. (1,016 mm) to match the dimensions of the posts evaluated during bogie testing.

Even though the steel sockets are not needed for installation of the system in concrete, the 2³/₄-in. x 1-in. x ¹/₄-in. steel standoffs welded to the sides of the S3x5.7 (S76x8.5) posts are still recommended for future installations. These post standoffs were originally developed as shims to prevent excess movement of the posts within the socket tube. However, full-scale testing of these posts within both the mow strip system and the original MGS bridge rail system illustrated that the welded standoff plates created stress concentrations in the post during weak-axis bending and led to tearing of the upstream flanges. Thus, the post bent over as though it was hinged at groundline once the tearing had occurred. This phenomenon is important as recent full-scale testing of small cars into weak-post systems has shown a propensity to result in floor pan tearing as the vehicle traverses over the top of weak posts during redirection [18-19]. Welding these standoff plates to weak posts will encourage the posts to tear and lie flat on the ground instead of rebounding upward and penetrating into the occupant compartment. Accordingly, the plates

should be welded so that the top of the plate is even with the groundline, or 40 in. (1,016 mm) from the bottom of the post, as shown in Figure 91.

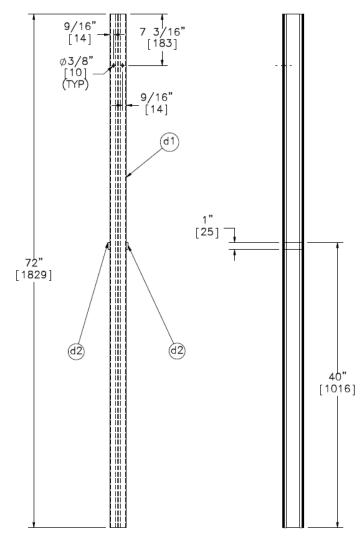

Figure 91. Recommended Post for Installations in Concrete Mow Strips

There is potential for the weak-post guardrail system to be implemented within an asphalt mow strip without the use of sockets, assuming that damage to the pavement was allowable. The sockets and shear plates were implemented only to distribute load throughout the asphalt and prevent pavement damage. Since this proved unsuccessful, the socket assemblies may provide minimal benefits to the system. Driving the posts directly through the asphalt may result in similar safety performance to that observed in the full-scale crash test. However, it may also slightly modify the stiffness of the system if the plastic hinge in the post forms at a different location (e.g., at the soil surface after the asphalt mow strip has fractured). Further testing and evaluation would be necessary to demonstrate that the system remains crashworthy in asphalt mow strips without the use of steel sockets.

Some users may still desire a guardrail system compatible with asphalt mow strips that does not damage the pavement. It is believed that this objective is obtainable, either through a variation of the weak-post guardrail system evaluated herein or a different configuration not yet evaluated. However, further design, testing, and analysis is required to develop such a system.

Regardless of the anchorage conditions for the S3x5.7 (S76x8.5) posts for this weak-post guardrail system, the use of 12-in. (305-mm) long backup plates behind the rail is recommended. The partial rail tearing observed during test no. MGSMS-1 was caused when the test vehicle impacted a post and caused it to deflect downstream and twist such that its flange contacted the bottom of the rail directly below the downstream splice bolts. Then, as the vehicle's right-front bumper and fender loaded the splice, the tear propagated to span half of the rail height. If a long backup plate had been installed at this location, the tear may have never occurred.

The original MGS bridge rail utilized 6-in. (152-mm) long backup plates at every post, including splice locations since the splice bolts are 8 in. (203 mm) apart. Unfortunately, the design drawings for the full-scale test specified 12-in. (305-mm) backup plates (taken from the non-blocked MGS drawings) instead of the 6-in. (152 mm) backup plates, and these larger backup plates could not be installed over the splice bolts, which are 8½ in. (216 mm) apart, without additional holes in the plate. As such, backup plates were not installed at locations where posts coincided with rail splices. The lack of backup plate material may have contributed to the partial rail tearing in test no. MGSMS-1. However, the tearing would have likely still occurred had 6-in. (152-mm) backup plates been utilized, because the 6-in. (152-mm) backup plates do

not extend below the splice bolts where the tear initiated. Similar rail tearing has been observed in other 2270P testing on S3x5.7 (S76x8.5) weak-post guardrail systems that utilized 5⁵/₈-in (143-mm) backup plates at all post locations [20].

To prevent rail tearing due to post contact near rail splices, a longer backup should be utilized to protect the rail around all posts, especially at splice locations. Therefore, the utilization of a 12-in. (305-mm) long backup plate is recommended for the weak-post guardrail system in mow strips, regardless of the type of mow strip. Further, the benefit of reducing the propensity for rail tearing could be achieved for other similar S3x5.7 (S76x8.5) weak-post guardrail systems, including the original MGS bridge rail and the weak-post guardrail attached to culverts, if 12-in. (305-mm) backup plates were utilized instead of 6-in. (152-mm) backup plates.

Since 12-in. (305-mm) long backup plates are unable to be installed at guardrail splices, holes or slots need to be cut into the backup plate to allow the guardrail bolts to pass through the plate. The backup plates could utilize the same splice bolt slot pattern that is currently punched into the ends of every guardrail segment. Utilizing this design, the backup plate could be attached to the guardrail and assembled as a part of the splice. Alternatively, a backup plate could be configured to fit over the back of assembled guardrail splices at the time of mounting the rail to a post. Under these conditions, the slots would need to be enlarged to fit around the splice bolts and nuts. Both of these design options are shown in Figure 92 and should be equally effective in reducing the risk of rail tearing.

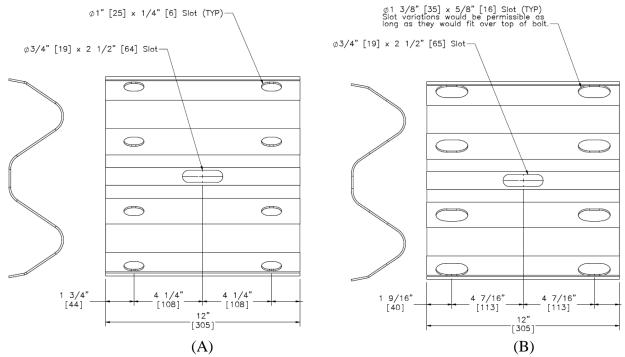

Figure 92. 12-in. (152-mm) Backup Plates with (A) Standard Splice Slots and (B) Enlarged Slots

The weak-post guardrail system was designed as part of a family of non-proprietary, 31in. (787-mm) high, W-beam guardrail systems commonly referred to as the MGS. The weak-post guardrail within mow strip systems was designed with a similar lateral stiffness and overall system performance as the original MGS and MGS bridge rail. Therefore, a stiffness transition between the weak-post guardrail in mow strips system and adjacent standard MGS installations is unnecessary. A 75-in. (1.9-m) spacing is recommended between the last S3x5.7 (S76x8.5) weak post and the first standard guardrail post of the adjacent MGS installation. The adjacent MGS may be either blocked or non-blocked.

Finally, installations should be constructed with the guardrail terminals (or end anchorages) located a sufficient distance away from the weak-post guardrail system to prevent the two systems from interfering with the proper performance of one another. As such, the following implementation guidelines should be considered in addition to guardrail length of need requirements:

- 1. A recommended minimum length of 12 ft 6 in. (3.8 m) of standard MGS between the first S3x5.7 (S76x8.5) weak post and the interior end of an acceptable TL-3 guardrail end terminal.
- A recommended minimum barrier length of 50 ft (15.2 m) before the first S3x5.7 (S76x8.5) weak post, which includes standard MGS and a crashworthy guardrail end terminal. This guidance applies to the downstream end as well.
- For flared guardrail applications, a recommended minimum length of 25 ft (7.6 m) between the first S3x5.7 (S76x8.5) weak post and the start of the flared section (i.e. bend between flared and tangent sections).

Jim C. Holloway [jholloway1@unl.edu] Thursday, July 25, 2013 10:11 AM Shaun Tighe FW: Midwest Roadside Safety Invoice

----Original Message-----From: Judy Miller [mailto:catherandsons@futuretk.com] Sent: Thursday, July 11, 2013 3:45 PM To: Jim Holloway Subject: RE: Midwest Roadside Safety Invoice

>Jim; This is what my records show for the mixed used on your project...let me know if you need it in a different format...Thanks, Judy

```
25% - 3A Gravel
28% - 1/4" Dry Chip Limestone
12% - 3/4" Clean Limestone
30% - RAP
5% - RAS
5.6% - PG58-28 asphaltic cement
```

Hello Judy, can you email me the mix design, not sure if they have gotten > back to you yet or not? > > -----Original Message-----> From: Judy Miller [mailto:catherandsons@futuretk.com] > Sent: Friday, June 28, 2013 1:24 PM > To: Jim Holloway > Subject: RE: Midwest Roadside Safety Invoice > >>I will get with Rick or Mike for the mix design used on your project >>and > let you know...did I do the billing correctly? > > Hello Judy, >> >> I was hoping that the invoice would show the specific mix type that >> was used. Can you determine that for me and send it to me on a >> separate document, do you have a standard method of supplying mix >> specification, like super paved shoulder, or binder, or base mix? >> >> Thanks >> >> Jim C. Holloway >> Research and Development Test Site Manager Midwest Roadside Safety >> Facility (MwRSF) University of Nebraska - Lincoln >> 4800 NW 35th Street >> Lincoln, NE 68524

Appendix B. Bogie Test Results

The results of the recorded data from each accelerometer for every dynamic component test are provided in the summary sheets found in this appendix. Summary sheets include acceleration, velocity, and deflection vs. time plots, as well as force vs. deflection and energy vs. deflection plots.
